---

op_cond *Conditionally applies* `true_fn` *or* `false_fn`.

---

## Description

Conditionally applies `true_fn` or `false_fn`.

## Usage

```
op_cond(pred, true_fn, false_fn)
```

## Arguments

| | |
|---|---|
| `pred` | Boolean scalar type |
| `true_fn` | Callable returning the output for the `pred == TRUE` case. |
| `false_fn` | Callable returning the output for the `pred == FALSE` case. |

## Value

The output of either `true_fn` or `false_fn` depending on pred.

## Examples

```
fn <- tensorflow::tf_function(function(x) {
  op_cond(x > 0,
    true_fn = \() x + 1,
    false_fn = \() x - 1)
})

fn(tensorflow::as_tensor(1))

## tf.Tensor(2.0, shape=(), dtype=float64)

fn(tensorflow::as_tensor(-1))

## tf.Tensor(-2.0, shape=(), dtype=float64)

#
# Conditional side-effect (print only, no return value).
file <- tempfile(fileext = ".txt")
fn <- tensorflow::tf_function(function(epochs) {
  op_fori_loop(
    0, epochs,
    body_fun = \(epoch, state) {
      op_cond(epoch %% 20 == 0,
              \() {
                tensorflow::tf$print(
                  "epoch:", epoch,
                  output_stream = paste0("file://", file))
                NULL
              },
              \() {NULL})
      state
    },
    init_val = tensorflow::as_tensor(0, "float32"))
})

fn(tensorflow::as_tensor(100, "float32"))

## tf.Tensor(0.0, shape=(), dtype=float32)

readLines(file)

## [1] "epoch: 0"  "epoch: 20" "epoch: 40" "epoch: 60" "epoch: 80"

# cleanup
unlink(file)
```

op_conj *Returns the complex conjugate, element-wise.*

---

## Description

The complex conjugate of a complex number is obtained by changing the sign of its imaginary part.

## Usage

```
op_conj(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

The complex conjugate of each element in x.

op_conv *General N-D convolution.*

---

## Description

This ops supports 1D, 2D and 3D convolution.

## Usage

```
op_conv(
  inputs,
  kernel,
  strides = 1L,
  padding = "valid",
  data_format = NULL,
  dilation_rate = 1L
)
```

## Arguments

| | |
|---|---|
| inputs | Tensor of rank N+2. inputs has shape (batch_size,) + inputs_spatial_shape + (num_channels,) if data_format = "channels_last", or (batch_size, num_channels) + inputs_spatial_shape if data_format = "channels_first". |
| kernel | Tensor of rank N+2. kernel has shape (kernel_spatial_shape, num_input_channels, num_output_ num_input_channels should match the number of channels in inputs. |
| strides | int or int tuple/list of len(inputs_spatial_shape), specifying the strides of the convolution along each spatial dimension. If strides is int, then every spatial dimension shares the same strides. Defaults to 1. |

| | |
|---|---|
| padding | string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides = 1. |
| data_format | A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format = "channels_last", inputs is of shape (batch_size, ..., channels) while if data_format = "channels_first", inputs is of shape (batch_size, channels, ...). |
| dilation_rate | int or int tuple/list of len(inputs_spatial_shape), specifying the dilation rate to use for dilated convolution. If dilation_rate is int, then every spatial dimension shares the same dilation_rate. |

## Value

A tensor of rank N+2, the result of the conv operation.

op_convert_to_numpy *Convert a tensor to an R or NumPy array.*

---

## Description

Convert a tensor to an R or NumPy array.

## Usage

```
op_convert_to_numpy(x)

op_convert_to_array(x)
```

## Arguments

| | |
|---|---|
| x | A tensor. |

## Value

A NumPy array or R array.

---

`op_convert_to_tensor` *Convert an array to a tensor.*

---

## Description

Native tensors for the current backend or left unchanged unless the `dtype`, `sparse` or `ragged` arguments are set.

## Usage

```
op_convert_to_tensor(x, dtype = NULL, sparse = NULL, ragged = NULL)
```

## Arguments

| | |
|---|---|
| `x` | An R or NumPy array (can be nested) or a backend tensor. |
| `dtype` | The target type. If `NULL`, the type of `x` is used. |
| `sparse` | Whether to keep sparse tensors. `FALSE` will cause sparse tensors to be densified. The default value of `NULL` means that sparse tensors are kept only if the backend supports them. |
| `ragged` | Whether to keep ragged tensors. `FALSE` will cause ragged tensors to be densified. The default value of `NULL` means that ragged tensors are kept only if the backend supports them. |

## Value

A backend tensor of the specified `dtype` and sparseness.

## Examples

```
x <- array(c(1, 2, 3))
y <- op_convert_to_tensor(x)
y
```

```
## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)
```

```
op_convert_to_tensor(c(1, 3, 2, 0), "int32")
```

```
## tf.Tensor([1 3 2 0], shape=(4), dtype=int32)
```

`op_conv_transpose` *General N-D convolution transpose.*

---

## Description

Also known as de-convolution. This ops supports 1D, 2D and 3D convolution.

## Usage

```
op_conv_transpose(
  inputs,
  kernel,
  strides = 1L,
  padding = "valid",
  output_padding = NULL,
  data_format = NULL,
  dilation_rate = 1L
)
```

## Arguments

| | |
|---|---|
| `inputs` | Tensor of rank N+2. `inputs` has shape `(batch_size,) + inputs_spatial_shape + (num_channels,)` if `data_format = "channels_last"`, or `(batch_size, num_channels) + inputs_spatial_shape` if `data_format = "channels_first"`. |

| | |
|---|---|
| kernel | Tensor of rank N+2. kernel has shape [kernel_spatial_shape, num_output_channels, num_input_ num_input_channels should match the number of channels in inputs. |
| strides | int or int tuple/list of len(inputs_spatial_shape), specifying the strides of the convolution along each spatial dimension. If strides is int, then every spatial dimension shares the same strides. |
| padding | string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides = 1. |
| output_padding | int or int tuple/list of len(inputs_spatial_shape), specifying the amount of padding along the height and width of the output tensor. Can be a single integer to specify the same value for all spatial dimensions. The amount of output padding along a given dimension must be lower than the stride along that same dimension. If set to NULL (default), the output shape is inferred. |
| data_format | A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format = "channels_last", inputs is of shape (batch_size, ..., channels) while if data_format = "channels_first", inputs is of shape (batch_size, channels, ...). |
| dilation_rate | int or int tuple/list of len(inputs_spatial_shape), specifying the dilation rate to use for dilated convolution. If dilation_rate is int, then every spatial dimension shares the same dilation_rate. |

## Value

A tensor of rank N+2, the result of the conv operation.

op_copy *Returns a copy of* x.

---

## Description

Returns a copy of x.

## Usage

```
op_copy(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A copy of x.

## See Also

`op_corrcoef` *Compute the Pearson correlation coefficient matrix.*

---

## Description

Compute the Pearson correlation coefficient matrix.

## Usage

```
op_corrcoef(x)
```

## Arguments

| | |
|---|---|
| `x` | A 2D tensor of shape `(N, D)`, where `N` is the number of variables and `D` is the number of observations. |

## Value

A tensor of shape `(N, N)` representing the correlation matrix.

## Examples

```
x <- op_array(matrix(c(1, 2, 3,
                       2, 3, 4), nrow = 2, byrow = TRUE))
op_corrcoef(x)

## tf.Tensor(
## [[1. 1.]
##  [1. 1.]], shape=(2, 2), dtype=float64)
```

`op_correlate` *Compute the cross-correlation of two 1-dimensional tensors.*

---

## Description

Compute the cross-correlation of two 1-dimensional tensors.

## Usage

```
op_correlate(x1, x2, mode = "valid")
```

## Arguments

| | |
|---|---|
| `x1` | First 1-dimensional input tensor of length M. |

| | |
|---|---|
| x2 | Second 1-dimensional input tensor of length N. |
| mode | Either "valid", "same" or "full". By default the mode is set to "valid", which returns an output of length max(M, N) - min(M, N) + 1. "same" returns an output of length max(M, N). "full" mode returns the convolution at each point of overlap, with an output length of N+M-1. |

## Value

Output tensor, cross-correlation of x1 and x2.

op_cos *Cosine, element-wise.*

---

## Description

Cosine, element-wise.

## Usage

```
op_cos(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

The corresponding cosine values.

## See Also

op_cosh *Hyperbolic cosine, element-wise.*

---

## Description

Hyperbolic cosine, element-wise.

## Usage

```
op_cosh(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor of same shape as x.

---

`op_count_nonzero` *Counts the number of non-zero values in* `x` *along the given* `axis`.

---

## Description

If no axis is specified then all non-zeros in the tensor are counted.

## Usage

```
op_count_nonzero(x, axis = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Axis or a tuple of axes along which to count the number of non-zeros. Defaults to `NULL`. |

## Value

An integer or a tensor of integers.

## Examples

```
x <- op_array(rbind(c(0, 1, 7, 0),
                    c(3, 0, 2, 19)))
op_count_nonzero(x)

## tf.Tensor(5, shape=(), dtype=int32)

op_count_nonzero(x, axis = 1)

## tf.Tensor([1 1 2 1], shape=(4), dtype=int32)

op_count_nonzero(x, axis = 2)

## tf.Tensor([2 3], shape=(2), dtype=int32)
```

---

`op_cross` *Returns the cross product of two (arrays of) vectors.*

---

## Description

The cross product of x1 and x2 in R^3 is a vector perpendicular to both x1 and x2. If x1 and x2 are arrays of vectors, the vectors are defined by the last axis of x1 and x2 by default, and these axes can have dimensions 2 or 3.

Where the dimension of either x1 or x2 is 2, the third component of the input vector is assumed to be zero and the cross product calculated accordingly.

In cases where both input vectors have dimension 2, the z-component of the cross product is returned.

## Usage

```
op_cross(x1, x2, axisa = -1L, axisb = -1L, axisc = -1L, axis = NULL)
```

## Arguments

| | |
|---|---|
| x1 | Components of the first vector(s). |
| x2 | Components of the second vector(s). |
| axisa | Axis of x1 that defines the vector(s). Defaults to -1. |
| axisb | Axis of x2 that defines the vector(s). Defaults to -1. |
| axisc | Axis of the result containing the cross product vector(s). Ignored if both input vectors have dimension 2, as the return is scalar. By default, the last axis. |
| axis | If defined, the axis of x1, x2 and the result that defines the vector(s) and cross product(s). Overrides axisa, axisb and axisc. |

## Value

Vector cross product(s).

## Note

Torch backend does not support two dimensional vectors, or the arguments axisa, axisb and axisc. Use axis instead.

`op_ctc_decode` *Decodes the output of a CTC model.*

---

## Description

Decodes the output of a CTC model.

## Usage

```
op_ctc_decode(
  inputs,
  sequence_lengths,
  strategy = "greedy",
  beam_width = 100L,
  top_paths = 1L,
  merge_repeated = TRUE,
  mask_index = 1L
)
```

## Arguments

| | |
|---|---|
| `inputs` | A tensor of shape `(batch_size, max_length, num_classes)` containing the logits (the output of the model). They should *not* be normalized via softmax. |
| `sequence_lengths` | A tensor of shape `(batch_size)` containing the sequence lengths for the batch. |
| `strategy` | A string for the decoding strategy. Supported values are `"greedy"` and `"beam_search"`. |
| `beam_width` | An integer scalar beam width used in beam search. Defaults to `100`. |
| `top_paths` | An integer scalar, the number of top paths to return. Defaults to `1`. |
| `merge_repeated` | A boolean scalar, whether to merge repeated labels in the output. Defaults to `TRUE`. |
| `mask_index` | An integer scalar, the (1-based) index of the mask character in the vocabulary. Defaults to `1`. |

## Value

A list containing:

- The tensor representing the list of decoded sequences. If `strategy="greedy"`, the shape is `(1, batch_size, max_length)`. If `strategy="beam_search"`, the shape is `(top_paths, batch_size, max_length` Note that: `-1` indicates the blank label.
- If `strategy="greedy"`, a tensor of shape `(batch_size, 1)` representing the negative of the sum of the probability logits for each sequence. If `strategy="beam_search"`, a tensor of shape `(batch_size, top_paths)` representing the log probability for each sequence.

`op_ctc_loss` *CTC (Connectionist Temporal Classification) loss.*

---

## Description

CTC (Connectionist Temporal Classification) loss.

## Usage

```
op_ctc_loss(target, output, target_length, output_length, mask_index = 1L)
```

## Arguments

| | |
|---|---|
| `target` | A tensor of shape `(batch_size, max_length)` containing the true labels in integer format. |

| | |
|---|---|
| output | A tensor of shape (batch_size, max_length, num_classes) containing logits (the output of your model). |
| target_length | A tensor of shape (batch_size) containing the true label lengths. |
| output_length | A tensor of shape (batch_size) containing the output lengths. |
| mask_index | The index of the mask character in the vocabulary. Defaults to 1 (the first element in vocabulary). |

## Value

A tensor, shape (batch_size), of loss values.

op_cumprod *Return the cumulative product of elements along a given axis.*

---

## Description

Return the cumulative product of elements along a given axis.

## Usage

```
op_cumprod(x, axis = NULL, dtype = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis along which the cumulative product is computed. By default the input is flattened. |
| dtype | dtype of returned tensor. Defaults to x$dtype. |

## Value

Output tensor.

op_cumsum *Returns the cumulative sum of elements along a given axis.*

---

## Description

Returns the cumulative sum of elements along a given axis.

## Usage

```
op_cumsum(x, axis = NULL, dtype = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis along which the cumulative sum is computed. By default the input is flattened. |
| dtype | dtype of returned tensor. Defaults to x$dtype. |

## Value

Output tensor.

---

`op_custom_gradient` *Decorator to define a function with a custom gradient.*

---

## Description

This decorator allows fine grained control over the gradients of a sequence for operations. This may be useful for multiple reasons, including providing a more efficient or numerically stable gradient for a sequence of operations.

## Usage

```
op_custom_gradient(f)
```

## Arguments

| | |
|---|---|
| `f` | Function `f(...)` that returns a tuple `(output, grad_fn)` where:<br>• `...` is a sequence of unnamed arguments, each a tensor input or nested structure of tensor inputs to the function.<br>• `output` is a (potentially nested structure of) tensor outputs of applying operations in forward_fn `f()` to `...`.<br>• `grad_fn` is a function with the signature `grad_fn(..., upstream)` which returns a list of tensors the same size as (flattened) `...`: the derivatives of tensors in `output` with respect to the tensors in `...`. `upstream` is a tensor or sequence of tensors holding the initial value gradients for each tensor in `output`. |

## Value

A function `h(...)` which returns the same value as `f(...)[[1]]` and whose gradient is determined by `f(...)[[2]]`.

## Example

Backend-agnostic example.

```
log1pexp <- op_custom_gradient(\(x) {

    e <- op_exp(x)

    grad <- function(..., upstream = NULL) {
      upstream <- upstream %||% ..1
      op_multiply(upstream, 1.0 - 1.0 / op_add(1, e))
```

```
    }

    tuple(op_log(1 + e), grad)

})

if(config_backend() == "tensorflow") {
  tf <- tensorflow::tf
  x <- op_convert_to_tensor(100.0)
  with(tf$GradientTape() %as% tape, {
    tape$watch(x)
    y <- log1pexp(x)
  })
  dy_dx <- tape$gradient(y, x)
  stopifnot(as.numeric(dy_dx) == 1)
}
```

## Note

Note that the grad function that returns gradient computation requires ... as well as an upstream named argument, depending on the backend being set. With the JAX and TensorFlow backends, it requires only one argument, whereas it might use the upstream argument in the case of the PyTorch backend.

When working with TensorFlow/JAX backend, grad(upstream) is sufficient. With PyTorch, the grad function requires ... as well as upstream, e.g. grad <- \(..., upstream). Follow the example above to use op_custom_gradient() in a way that is compatible with all backends.

op_deg2rad *Convert angles from degrees to radians.*

## Description

The conversion is defined as: `rad = deg * (pi / 180)`.

## Usage

```
op_deg2rad(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor of angles in degrees. |

## Value

A tensor containing angles converted to radians.

## Examples

```
op_deg2rad(c(0, 90, 180))

## tf.Tensor([0.        1.5707964 3.1415927], shape=(3), dtype=float32)
```

op_depthwise_conv *General N-D depthwise convolution.*

## Description

This ops supports 1D and 2D depthwise convolution.

## Usage

```
op_depthwise_conv(
  inputs,
  kernel,
  strides = 1L,
  padding = "valid",
  data_format = NULL,
  dilation_rate = 1L
)
```

## Arguments

| | |
|---|---|
| inputs | Tensor of rank N+2. inputs has shape (batch_size,) + inputs_spatial_shape + (num_channels,) if data_format = "channels_last", or (batch_size, num_channels) + inputs_spatial_shape if data_format = "channels_first". |
| kernel | Tensor of rank N+2. kernel has shape [kernel_spatial_shape, num_input_channels, num_channel num_input_channels should match the number of channels in inputs. |
| strides | int or int tuple/list of len(inputs_spatial_shape), specifying the strides of the convolution along each spatial dimension. If strides is int, then every spatial dimension shares the same strides. |
| padding | string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides = 1. |
| data_format | A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format = "channels_last", inputs is of shape (batch_size, ..., channels) while if data_format = "channels_first", inputs is of shape (batch_size, channels, ...). |
| dilation_rate | int or int tuple/list of len(inputs_spatial_shape), specifying the dilation rate to use for dilated convolution. If dilation_rate is int, then every spatial dimension shares the same dilation_rate. |

## Value

A tensor of rank N+2, the result of the depthwise conv operation.

`op_det` *Computes the determinant of a square tensor.*

---

## Description

Computes the determinant of a square tensor.

## Usage

```
op_det(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor of shape `(..., M, M)`. |

## Value

A tensor of shape `(...)` representing the determinant of `x`.

op_zeros_like()

---

`op_diag` *Extract a diagonal or construct a diagonal array.*

---

## Description

Extract a diagonal or construct a diagonal array.

## Usage

```
op_diag(x, k = 0L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. If `x` is 2-D, returns the k-th diagonal of `x`. If `x` is 1-D, return a 2-D tensor with `x` on the k-th diagonal. |
| `k` | The diagonal to consider. Defaults to `0`. Use `k > 0` for diagonals above the main diagonal, and `k < 0` for diagonals below the main diagonal. |

## Value

The extracted diagonal or constructed diagonal tensor.

## Examples

```
x <- op_arange(9L) |> op_reshape(c(3, 3))
x

## tf.Tensor(
## [[1 2 3]
##  [4 5 6]
##  [7 8 9]], shape=(3, 3), dtype=int32)

op_diag(x)

## tf.Tensor([1 5 9], shape=(3), dtype=int32)

op_diag(x, k = 1)

## tf.Tensor([2 6], shape=(2), dtype=int32)

op_diag(x, k = -1)

## tf.Tensor([4 8], shape=(2), dtype=int32)

op_diag(op_diag(x))

## tf.Tensor(
## [[1 0 0]
##  [0 5 0]
##  [0 0 9]], shape=(3, 3), dtype=int32)
```

---

`op_diagflat` *Create a two-dimensional array with the flattened input diagonal.*

---

## Description

the k-th diagonal.

## Usage

```
op_diagflat(x, k = 0L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor to be flattened and placed on the diagonal. |
| `k` | The diagonal to place the flattened input. Defaults to `0`. Use `k > 0` for diagonals above the main diagonal, and `k < 0` for diagonals below the main diagonal. |

## Value

A 2-D tensor with the flattened input on the specified diagonal.

---

op_diagonal *Return specified diagonals.*

---

## Description

If x is 2-D, returns the diagonal of x with the given offset, i.e., the collection of elements of the form x[i, i+offset].

If x has more than two dimensions, the axes specified by axis1 and axis2 are used to determine the 2-D sub-array whose diagonal is returned.

The shape of the resulting array can be determined by removing axis1 and axis2 and appending an index to the right equal to the size of the resulting diagonals.

## Usage

```
op_diagonal(x, offset = 0L, axis1 = 1L, axis2 = 2L)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| offset | Offset of the diagonal from the main diagonal. Can be positive or negative. Defaults to 0 (main diagonal). |
| axis1 | Axis to be used as the first axis of the 2-D sub-arrays. Defaults to 1 (first axis). |
| axis2 | Axis to be used as the second axis of the 2-D sub-arrays. Defaults to 2 (second axis). |

## Value

Tensor of diagonals.

## Examples

```
x <- op_arange(4L) |> op_reshape(c(2, 2))
x

## tf.Tensor(
## [[1 2]
##  [3 4]], shape=(2, 2), dtype=int32)
```

```
op_diagonal(x)
```

```
## tf.Tensor([1 4], shape=(2), dtype=int32)
```

```
op_diagonal(x, offset = 1)
```

```
## tf.Tensor([2], shape=(1), dtype=int32)
```

```
x <- op_array(1:8) |> op_reshape(c(2, 2, 2))
x
```

```
## tf.Tensor(
## [[[1 2]
##   [3 4]]
##
##  [[5 6]
##   [7 8]]], shape=(2, 2, 2), dtype=int32)
```

```
x |> op_diagonal(0)
```

```
## tf.Tensor(
## [[1 7]
##  [2 8]], shape=(2, 2), dtype=int32)
```

```
x |> op_diagonal(0, 1, 2) # same as above, the default
```

```
## tf.Tensor(
## [[1 7]
##  [2 8]], shape=(2, 2), dtype=int32)
```

```
x |> op_diagonal(0, 2, 3)
```

```
## tf.Tensor(
## [[1 4]
##  [5 8]], shape=(2, 2), dtype=int32)
```

---

`op_diff` *Calculate the n-th discrete difference along the given axis.*

---

## Description

The first difference is given by `out[i] = a[i+1] - a[i]` along the given axis, higher differences are calculated by using `diff` recursively.

## Usage

```
op_diff(a, n = 1L, axis = -1L)
```

## Arguments

| | |
|---|---|
| `a` | Input tensor. |
| `n` | The number of times values are differenced. Defaults to `1`. |
| `axis` | Axis to compute discrete difference(s) along. Defaults to `-1` (last axis). |

## Value

Tensor of diagonals.

## Examples

```
x <- op_array(c(1, 2, 4, 7, 0))
op_diff(x)

## tf.Tensor([ 1.  2.  3. -7.], shape=(4), dtype=float32)

op_diff(x, n = 2)

## tf.Tensor([  1.   1. -10.], shape=(3), dtype=float32)

x <- op_array(rbind(c(1, 3, 6, 10),
                    c(0, 5, 6, 8)))
op_diff(x)

## tf.Tensor(
## [[2. 3. 4.]
##  [5. 1. 2.]], shape=(2, 3), dtype=float64)

op_diff(x, axis = 1)

## tf.Tensor([[-1.  2.  0. -2.]], shape=(1, 4), dtype=float64)
```

op_digitize *Returns the indices of the bins to which each value in* x *belongs.*

## Description

Returns the indices of the bins to which each value in x belongs.

## Usage

```
op_digitize(x, bins, zero_indexed = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input array to be binned. |
| bins | Array of bins. It has to be one-dimensional and monotonically increasing. |
| zero_indexed | If TRUE, the returned indices are zero-based (0 encodes to first bin); if FALSE (default), the returned indices are one-based (1 encodes the first bin). |

## Value

Output array of indices, of same shape as x.

## Examples

```
x <- op_array(c(-1,    0, 1,    3, 3.5,      4.5,  1.6,    8))
bins <- array(c(    0,       3,         4.5,            7))
op_digitize(x, bins)

## tf.Tensor([1 2 2 3 3 4 2 5], shape=(8), dtype=int32)
```

---

op_divide *Divide arguments element-wise.*

---

## Description

Note that this function is automatically called when using the R operator * with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_divide(x, 2)

## tf.Tensor([0.5 1.  1.5 2. ], shape=(4), dtype=float32)

x / 2

## tf.Tensor([0.5 1.  1.5 2. ], shape=(4), dtype=float32)
```

## Usage

```
op_divide(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, the quotient x1/x2, element-wise.

## Example

```
op_divide(3, 2)

## tf.Tensor(1.5, shape=(), dtype=float32)
```

---

`op_divide_no_nan` *Safe element-wise division which returns 0 where the denominator is 0.*

---

## Description

Safe element-wise division which returns 0 where the denominator is 0.

## Usage

```
op_divide_no_nan(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

The quotient `x1/x2`, element-wise, with zero where x2 is zero.

`op_dot` *Dot product of two tensors.*

---

## Description

- If both `x1` and `x2` are 1-D tensors, it is inner product of vectors (without complex conjugation).
- If both `x1` and `x2` are 2-D tensors, it is matrix multiplication.
- If either `x1` or `x2` is 0-D (scalar), it is equivalent to `x1 * x2`.
- If `x1` is an N-D tensor and `x2` is a 1-D tensor, it is a sum product over the last axis of `x1` and `x2`.
- If `x1` is an N-D tensor and `x2` is an M-D tensor (where `M >= 2`), it is a sum product over the last axis of `x1` and the second-to-last axis of `x2`: `dot(x1, x2)[i,j,k,m] = sum(a[i,j,:] * b[k,:,m])`.

## Usage

```
op_dot(x1, x2)
```

## Arguments

| | |
|---|---|
| `x1` | First argument. |
| `x2` | Second argument. |

## Value

Dot product of `x1` and `x2`.

## Note

Torch backend does not accept 0-D tensors as arguments.

---

`op_dot_product_attention` *Scaled dot product attention function.*

---

## Description

Computes the attention function on Q (`query`), K (`key`), and V(`value`): `attention(Q, K, V) = softmax(Q * K / sqrt(d)) * V`. If we define `logits` as the output of `Q * K` and the `probs` as the output of `softmax`.

Throughout this function, we utilize the following notation to represent the shape of array:

- B: batch size
- S: length of the key/value
- T: length of the query
- N: number of attention heads

- H: dimensions of each attention head
- K: number of key/value heads
- G: number of groups, which equals to `N // K`

## Usage

```
op_dot_product_attention(
  query,
  key,
  value,
  bias = NULL,
  mask = NULL,
  scale = NULL,
  is_causal = FALSE,
  flash_attention = NULL,
  attn_logits_soft_cap = NULL
)
```

## Arguments

| | |
|---|---|
| `query` | The query array with the shape of `(B, T, N, H)`. |
| `key` | The key array with the shape of `(B, S, K, H)`. When `K` equals `N`, multi-headed attention (MHA) is performed. Otherwise, grouped query attention (GQA) is performed if `N` is a multiple of `K`. and multi-query attention (MQA) is performed if `K==1` (a special case of GQA). |
| `value` | The value array with the same shape of `key`. |
| `bias` | Optional bias array to be added to logits. The shape must be broadcastable to `(B, N, T, S)`. |
| `mask` | Optional mask array used to filter out logits. It is a boolean mask where `TRUE` indicates the element should take part in attention. For an additive mask, users should pass it to bias. The shape must be broadcastable to `(B, N, T, S)`. |
| `scale` | Optional scale for the logits. If `NULL`, the scale will be set to `1.0 / sqrt(H)`. |
| `is_causal` | Whether to apply causal mask. |
| `flash_attention` | Whether to use flash attention. If `NULL`, it will attempt to use flash attention if the required conditions are met. Typically, the inputs must be in float16 and bfloat16 dtype and the input layout requirements may vary depending on the backend. |
| `attn_logits_soft_cap` | Optional numeric cap on the attention logits before softmax. Only supported on the JAX TPU backend. |

## Value

An array of the attention output with the same shape of `query`.

## Examples

```
query = random_normal(c(2, 4, 8, 16))
key = random_normal(c(2, 6, 8, 16))
value = random_normal(c(2, 6, 8, 16))
op_dot_product_attention(query, key, value) |> op_shape()

## shape(2, 4, 8, 16)
```

---

op_dtype *Return the dtype of the tensor input as a standardized string.*

---

## Description

Note that due to the standardization, the dtype will not compare equal to the backend-specific version of the dtype.

## Usage

```
op_dtype(x)
```

## Arguments

| | |
|---|---|
| x | A tensor. This function will try to access the `dtype` attribute of the input tensor. |

## Value

A string indicating the dtype of the input tensor, e.g. `"float32"`.

## Examples

```
x <- op_zeros(c(8, 12))
op_dtype(x)

## [1] "float32"
```

op_eig *Computes the eigenvalues and eigenvectors of a square matrix.*

---

## Description

Computes the eigenvalues and eigenvectors of a square matrix.

## Usage

```
op_eig(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor of shape (..., M, M). |

## Value

A list of two tensors: a tensor of shape (..., M) containing eigenvalues and a tensor of shape (..., M, M) containing eigenvectors.

---

`op_einsum` *Evaluates the Einstein summation convention on the operands.*

---

## Description

Evaluates the Einstein summation convention on the operands.

## Usage

```
op_einsum(subscripts, ...)
```

## Arguments

| | |
|---|---|
| `subscripts` | Specifies the subscripts for summation as comma separated list of subscript labels. An implicit (classical Einstein summation) calculation is performed unless the explicit indicator `->` is included as well as subscript labels of the precise output form. |
| `...` | The operands to compute the Einstein sum of as unnamed arguments. Additional named arguments are forwarded to the underlying backend. |

## Value

The calculation based on the Einstein summation convention.

## Examples

```
a <- op_arange(25) |> op_reshape(c(5, 5))
b <- op_arange(5)
c <- op_arange(6) |> op_reshape(c(2, 3))
```

Trace of a matrix:

```
op_einsum("ii", a)
op_trace(a)

## tf.Tensor(65.0, shape=(), dtype=float32)
## tf.Tensor(65.0, shape=(), dtype=float32)
```

Extract the diagonal:

```
op_einsum("ii -> i", a)
op_diag(a)

## tf.Tensor([ 1.  7. 13. 19. 25.], shape=(5), dtype=float32)
## tf.Tensor([ 1.  7. 13. 19. 25.], shape=(5), dtype=float32)
```

Sum over an axis:

```
op_einsum("ij -> i", a)
op_sum(a, axis = 2)

## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
```

For higher dimensional tensors summing a single axis can be done with ellipsis:

```
op_einsum("...j -> ...", a)
op_sum(a, axis = -1)

## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
## tf.Tensor([ 15.  40.  65.  90. 115.], shape=(5), dtype=float32)
```

Compute a matrix transpose or reorder any number of axes:

```
op_einsum("ji", c) # return c unchanged

## tf.Tensor(
## [[1. 2. 3.]
##  [4. 5. 6.]], shape=(2, 3), dtype=float32)

op_einsum("ij -> ji", c) # transpose
op_transpose(c)          # same as above
```

```
## tf.Tensor(
## [[1. 4.]
##  [2. 5.]
##  [3. 6.]], shape=(3, 2), dtype=float32)
## tf.Tensor(
## [[1. 4.]
##  [2. 5.]
##  [3. 6.]], shape=(3, 2), dtype=float32)
```

Matrix vector multiplication:

```
op_einsum("ij, j", a, b)
op_einsum("...j, j", a, b)
a %*% b
op_matmul(a, b)
```

```
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
## tf.Tensor([ 55. 130. 205. 280. 355.], shape=(5), dtype=float32)
```

op_elu *Exponential Linear Unit activation function.*

## Description

It is defined as:
`f(x) = alpha * (exp(x) - 1.) for x < 0`, `f(x) = x for x >= 0`.

## Usage

```
op_elu(x, alpha = 1)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| alpha | A scalar, slope of positive section. Defaults to `1.0`. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1., 0., 1.))
op_elu(x)
```

```
## tf.Tensor([-0.63212055  0.          1.        ], shape=(3), dtype=float32)
```

`op_empty` *Return a tensor of given shape and type filled with uninitialized data.*

---

## Description

Return a tensor of given shape and type filled with uninitialized data.

## Usage

```
op_empty(shape, dtype = NULL)
```

## Arguments

| | |
|---|---|
| `shape` | Shape of the empty tensor. |
| `dtype` | Desired data type of the empty tensor. |

## Value

The empty tensor.

op_equal *Returns* (x1 == x2) *element-wise.*

---

## Description

Note that this function is automatically called when using the R operator == with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_equal(x, 2)

## tf.Tensor([False  True False False], shape=(4), dtype=bool)

x == 2

## tf.Tensor([False  True False False], shape=(4), dtype=bool)
```

## Usage

```
op_equal(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | Tensor to compare. |
| x2 | Tensor to compare. |

## Value

Output tensor, element-wise comparison of x1 and x2.

`op_erf` *Computes the error function of* `x`*, element-wise.*

---

## Description

Computes the error function of `x`, element-wise.

## Usage

```
op_erf(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A tensor with the same dtype as x.

## Examples

```
x <- op_array(c(-3, -2, -1, 0, 1))
op_erf(x)
```

```
## tf.Tensor([-0.999978  -0.99532235 -0.84270084  0.        0.84270084], shape=(5), dtype=float32)
```

```
# array([-0.99998 , -0.99532, -0.842701,  0.,  0.842701], dtype=float32)
```

`op_erfinv` *Computes the inverse error function of* `x`*, element-wise.*

---

## Description

Computes the inverse error function of `x`, element-wise.

## Usage

```
op_erfinv(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

A tensor with the same dtype as `x`.

## Examples

```
x <- op_array(c(-0.5, -0.2, -0.1, 0.0, 0.3))
op_erfinv(x)
```

```
## tf.Tensor([-0.4769363  -0.17914344 -0.088856   0.         0.27246267], shape=(5), dtype=float32)
```

`op_exp` *Calculate the exponential of all elements in the input tensor.*

---

## Description

Calculate the exponential of all elements in the input tensor.

## Usage

```
op_exp(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

Output tensor, element-wise exponential of `x`.

op_exp2 *Calculate the base-2 exponential of all elements in the input tensor.*

---

## Description

Calculate the base-2 exponential of all elements in the input tensor.

## Usage

```
op_exp2(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, element-wise base-2 exponential of x.

op_expand_dims *Expand the shape of a tensor.*

---

## Description

Insert a new axis at the `axis` position in the expanded tensor shape.

## Usage

```
op_expand_dims(x, axis)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Position in the expanded axes where the new axis (or axes) is placed. |

## Value

Output tensor with the number of dimensions increased.

## See Also

op_expm1 *Calculate* `exp(x) - 1` *for all elements in the tensor.*

---

## Description

Calculate `exp(x) - 1` for all elements in the tensor.

## Usage

```
op_expm1(x)
```

## Arguments

| | |
|---|---|
| x | Input values. |

## Value

Output tensor, element-wise exponential minus one.

## See Also

---

op_extract_sequences *Expands the dimension of last axis into sequences of* sequence_length.

---

## Description

Slides a window of size sequence_length over the last axis of the input with a stride of sequence_stride, replacing the last axis with [num_sequences, sequence_length] sequences.

If the dimension along the last axis is N, the number of sequences can be computed by:
num_sequences = 1 + (N - sequence_length) // sequence_stride

## Usage

```
op_extract_sequences(x, sequence_length, sequence_stride)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| sequence_length | An integer representing the sequences length. |
| sequence_stride | An integer representing the sequences hop size. |

## Value

A tensor of sequences with shape [..., num_sequences, sequence_length].

## Examples

```
x <- op_convert_to_tensor(1:6)
op_extract_sequences(x, 3, 2)

## tf.Tensor(
## [[1 2 3]
##  [3 4 5]], shape=(2, 3), dtype=int32)
```

op_eye *Return a 2-D tensor with ones on the diagonal and zeros elsewhere.*

---

## Description

Return a 2-D tensor with ones on the diagonal and zeros elsewhere.

## Usage

```
op_eye(N, M = NULL, k = 0L, dtype = NULL)
```

## Arguments

| | |
|---|---|
| N | Number of rows in the output. |
| M | Number of columns in the output. If NULL, defaults to N. |
| k | Index of the diagonal: 0 (the default) refers to the main diagonal, a positive value refers to an upper diagonal, and a negative value to a lower diagonal. |
| dtype | Data type of the returned tensor. |

## Value

Tensor with ones on the k-th diagonal and zeros elsewhere.

`op_fft` *Computes the Fast Fourier Transform along last axis of input.*

---

## Description

Computes the Fast Fourier Transform along last axis of input.

## Usage

```
op_fft(x)
```

## Arguments

| | |
|---|---|
| x | list of the real and imaginary parts of the input tensor. Both tensors provided should be of floating type. |

## Value

A list containing two tensors - the real and imaginary parts of the output tensor.

## Examples

```
x = c(op_array(c(1., 2.)),
      op_array(c(0., 1.)))
op_fft(x)
```

```
## [[1]]
## tf.Tensor([ 3. -1.], shape=(2), dtype=float32)
##
## [[2]]
## tf.Tensor([ 1. -1.], shape=(2), dtype=float32)
```

`op_fft2` *Computes the 2D Fast Fourier Transform along the last two axes of input.*

---

## Description

Computes the 2D Fast Fourier Transform along the last two axes of input.

## Usage

```
op_fft2(x)
```

## Arguments

| | |
|---|---|
| x | list of the real and imaginary parts of the input tensor. Both tensors provided should be of floating type. |

## Value

A list containing two tensors - the real and imaginary parts of the output.

## Examples

```
x <- c(op_array(rbind(c(1, 2),
                      c(2, 1))),
       op_array(rbind(c(0, 1),
                      c(1, 0))))
op_fft2(x)
```

```
## [[1]]
## tf.Tensor(
## [[ 6.  0.]
##  [ 0. -2.]], shape=(2, 2), dtype=float64)
##
## [[2]]
## tf.Tensor(
## [[ 2.  0.]
##  [ 0. -2.]], shape=(2, 2), dtype=float64)
```

`op_flip` *Reverse the order of elements in the tensor along the given axis.*

---

## Description

The shape of the tensor is preserved, but the elements are reordered.

## Usage

```
op_flip(x, axis = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Axis or axes along which to flip the tensor. The default, `axis = NULL`, will flip over all of the axes of the input tensor. |

## Value

Output tensor with entries of `axis` reversed.

---

`op_floor` *Return the floor of the input, element-wise.*

---

## Description

The floor of the scalar `x` is the largest integer `i`, such that `i <= x`.

## Usage

```
op_floor(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

Output tensor, element-wise floor of `x`.

## See Also

---

op_floor_divide *Returns the largest integer smaller or equal to the division of inputs.*

---

## Description

Note that this function is automatically called when using the R operator `%/%` with a tensor.

```
(x <- op_arange(10))
```

```
## tf.Tensor([ 1.  2.  3.  4.  5.  6.  7.  8.  9. 10.], shape=(10), dtype=float32)
```

```
op_floor_divide(x, 2)
```

```
## tf.Tensor([0. 1. 1. 2. 2. 3. 3. 4. 4. 5.], shape=(10), dtype=float32)
```

```
x %/% 2
```

```
## tf.Tensor([0. 1. 1. 2. 2. 3. 3. 4. 4. 5.], shape=(10), dtype=float32)
```

## Usage

```
op_floor_divide(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | Numerator. |
| x2 | Denominator. |

## Value

Output tensor, `y <- floor(x1/x2)`

`op_fori_loop` *For loop implementation.*

---

## Description

For loop implementation.

## Usage

```
op_fori_loop(lower, upper, body_fun, init_val)
```

## Arguments

| | |
|---|---|
| `lower` | The initial value of the loop variable. |
| `upper` | The upper bound of the loop variable. |

| | |
|---|---|
| body_fun | A callable that represents the loop body. Must take two arguments: the loop variable and the loop state. The loop state should be updated and returned by this function. |
| init_val | The initial value of the loop state. |

## Value

The final state after the loop.

## Examples

```
lower <- 0L
upper <- 10L
body_fun <- function(i, state) state + i
init_state <- 0L
final_state <- op_fori_loop(lower, upper, body_fun, init_state)
final_state
```

```
## tf.Tensor(45, shape=(), dtype=int32)
```

`op_full` *Return a new tensor of given shape and type, filled with* `fill_value`.

---

## Description

Return a new tensor of given shape and type, filled with `fill_value`.

## Usage

```
op_full(shape, fill_value, dtype = NULL)
```

## Arguments

| | |
|---|---|
| shape | Shape of the new tensor. |
| fill_value | Fill value. |
| dtype | Desired data type of the tensor. |

## Value

Output tensor.

`op_full_like` *Return a full tensor with the same shape and type as the given tensor.*

---

## Description

Return a full tensor with the same shape and type as the given tensor.

## Usage

```
op_full_like(x, fill_value, dtype = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| fill_value | Fill value. |
| dtype | Overrides data type of the result. |

## Value

Tensor of fill_value with the same shape and type as x.

---

`op_gelu` *Gaussian Error Linear Unit (GELU) activation function.*

---

## Description

If `approximate` is `TRUE`, it is defined as: `f(x) = 0.5 * x * (1 + tanh(sqrt(2 / pi) * (x + 0.044715 * x^3)))`

Or if `approximate` is `FALSE`, it is defined as: `f(x) = x * P(X <= x) = 0.5 * x * (1 + erf(x / sqrt(2)))`, where `P(X) ~ N(0, 1)`.

## Usage

```
op_gelu(x, approximate = TRUE)
```

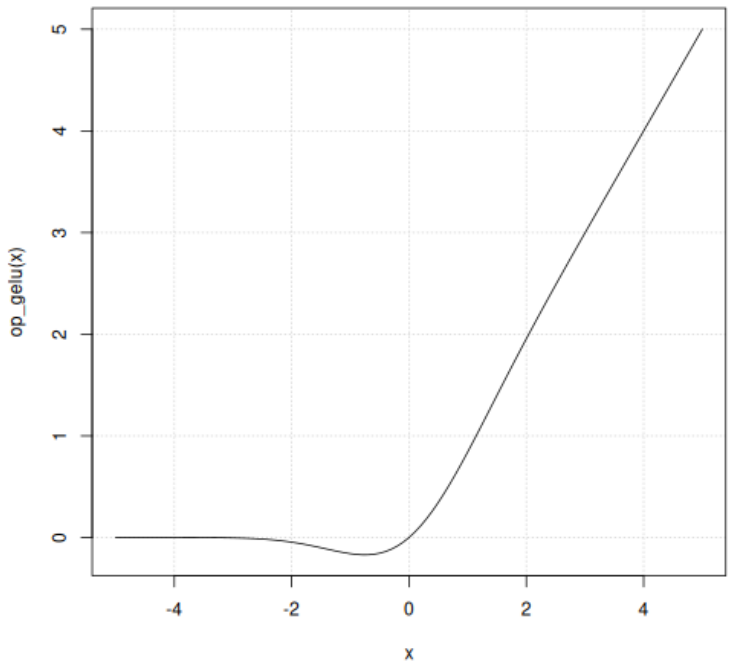
## Arguments

| | |
|---|---|
| x | Input tensor. |
| approximate | Approximate version of GELU activation. Defaults to TRUE. |

## Value

A tensor with the same shape as x.

## Examples



```
x <- op_array(c(-1., 0., 1.))
op_gelu(x)
```

```
## tf.Tensor([-0.158808  0.        0.841192], shape=(3), dtype=float32)
```

```
op_gelu(x, FALSE)
```

```
## tf.Tensor([-0.15865526  0.          0.8413447 ], shape=(3), dtype=float32)
```

```
x <- seq(-5, 5, .1)
plot(x, op_gelu(x),
     type = "l", #, frame.plot = FALSE,
     panel.first = grid())
```

---

op_get_item *Return* x[key].

---

## Description

Return `x[key]`.

## Usage

```
op_get_item(x, key)
```

## Arguments

| | |
|---|---|
| `x` | A dictionary-like object |
| `key` | Generally, a string, but most object with a `__hash__` method are acceptable. |

## Value

`key`.

## Note

Generally, calling `x[[key]]` or `x$key` is preferable.

---

op_glu *Gated Linear Unit (GLU) activation function.*

---

## Description

It is defined as:

`f(x) = a * sigmoid(b)` where `x` is split into `a` and `b` along the given axis.

## Usage

```
op_glu(x, axis = -1L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | The axis along which to split the input tensor. Defaults to `-1`. |

## Value

A tensor with the same shape as half of the input.

## Examples

```
x <- op_array(c(-1., 0., 1. , 1.))
op_glu(x)
```

```
## tf.Tensor([-0.7310586  0.       ], shape=(2), dtype=float32)
```

---

op_greater *Return the truth value of* x1 > x2 *element-wise.*

---

## Description

Note that this function is automatically called when using the R operator > with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_greater(x, 2)

## tf.Tensor([False False  True  True], shape=(4), dtype=bool)

x > 2

## tf.Tensor([False False  True  True], shape=(4), dtype=bool)
```

## Usage

```
op_greater(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise comparison of x1 and x2.

`op_greater_equal` *Return the truth value of* `x1 >= x2` *element-wise.*

---

## Description

Note that this function is automatically called when using the R operator >= with a tensor.

```
(x <- op_arange(4))
```

```
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
```

```
op_greater_equal(x, 2)
```

```
## tf.Tensor([False  True  True  True], shape=(4), dtype=bool)
```

```
x >= 2
```

```
## tf.Tensor([False  True  True  True], shape=(4), dtype=bool)
```

## Usage

```
op_greater_equal(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise comparison of x1 and x2.

op_hamming *Hamming window function.*

---

## Description

The Hamming window is defined as: `w[n] = 0.54 - 0.46 * cos(2 * pi * n / (N - 1))` for `0 <= n <= N - 1`.

## Usage

```
op_hamming(x)
```

## Arguments

| | |
|---|---|
| x | Length of the window. Must be a positive integer. |

## Value

A 1D tensor containing the window values.

## Examples

```
op_hamming(5)
```

```
## tf.Tensor([0.08000001 0.54     1.       0.54     0.08000001], shape=(5), dtype=float32)
```

op_hanning *Hanning window function.*

---

## Description

The Hanning window is defined as: `w[n] = 0.5 - 0.5 * cos(2 * pi * n / (N - 1))` for `0 <= n <= N - 1`.

## Usage

```
op_hanning(x)
```

## Arguments

| | |
|---|---|
| x | Length of the window. Must be a positive integer. |

## Value

A 1D tensor containing the window values.

## Examples

```
op_hanning(5)

## tf.Tensor([0.  0.5 1.  0.5 0. ], shape=(5), dtype=float32)
```

`op_hard_shrink` *Hard Shrink activation function.*

---

## Description

The Hard Shrink function is a thresholding operation defined as:

`f(x) = x` if `|x| > threshold`, `f(x) = 0` otherwise.

## Usage

```
op_hard_shrink(x, threshold = 0.5)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `threshold` | Threshold value. Defaults to 0.5. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-0.5, 0., 1.))
op_hard_shrink(x)

## tf.Tensor([0. 0. 1.], shape=(3), dtype=float32)
```

`op_hard_sigmoid` *Hard sigmoid activation function.*

---

## Description

It is defined as:
`0 if x < -2.5`, `1 if x > 2.5`, `(0.2 * x) + 0.5 if -2.5 <= x <= 2.5`.

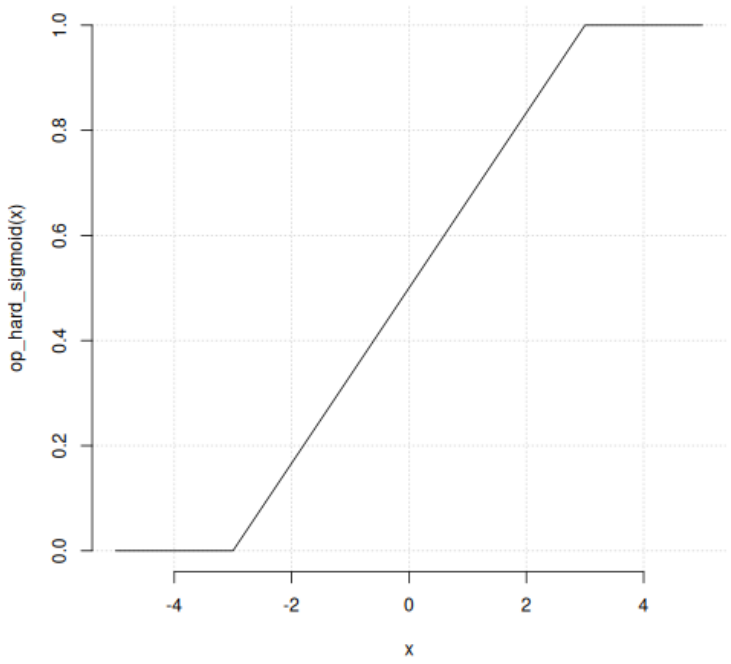
## Usage

```
op_hard_sigmoid(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value



A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1., 0., 1.))
op_hard_sigmoid(x)
```

```
## tf.Tensor([0.33333334 0.5        0.6666667 ], shape=(3), dtype=float32)
```

```
x <- as.array(seq(-5, 5, .1))
plot(x, op_hard_sigmoid(x),
     type = 'l', panel.first = grid(), frame.plot = FALSE)
```

`op_hard_silu` *Hard SiLU activation function, also known as Hard Swish.*

---

## Description

It is defined as:

- `0` if `if x < -3`
- `x` if `x > 3`
- `x * (x + 3) / 6` if `-3 <= x <= 3`

It's a faster, piecewise linear approximation of the silu activation.

## Usage

```
op_hard_silu(x)

op_hard_swish(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_convert_to_tensor(c(-3.0, -1.0, 0.0, 1.0, 3.0))
op_hard_silu(x)
```

```
## tf.Tensor([-0.      -0.33333333  0.       0.66666667  3.     ], shape=(5), dtype=float64)
```

op_hard_tanh *Applies the HardTanh function element-wise.*

---

## Description

It is defined as:
`f(x) = -1 for x < -1`, `f(x) = x for -1 <= x <= 1`, `f(x) = 1 for x > 1`.

## Usage

```
op_hard_tanh(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor of same shape as `x` where values are clamped between -1 and 1.

## Examples

```
x <- op_array(c(-2., -1., 0., 1., 2.))
op_hard_tanh(x)

## tf.Tensor([-1. -1.  0.  1.  1.], shape=(5), dtype=float32)
```

`op_heaviside` *Heaviside step function.*

---

## Description

The Heaviside step function is defined as: `heaviside(x1, x2) = 0` if `x1 < 0`, `heaviside(x1, x2) = 1` if `x1 > 0`, and `heaviside(x1, x2) = x2` if `x1 == 0`.

## Usage

```
op_heaviside(x1, x2)
```

## Arguments

| | |
|---|---|
| `x1` | Tensor input. |
| `x2` | Value to use when `x1 == 0`. |

## Value

A tensor broadcast from `x1` and `x2` containing `0`, `1`, or `x2`.

## Examples

```
x1 <- op_array(c(-2, 0, 3))
op_heaviside(x1, 0.5)

## tf.Tensor([0.  0.5 1. ], shape=(3), dtype=float32)
```

`op_histogram` *Computes a histogram of the data tensor* `x`.

---

## Description

Computes a histogram of the data tensor `x`.

## Usage

```
op_histogram(x, bins = 10L, range = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| bins | An integer representing the number of histogram bins. Defaults to 10. |
| range | A pair of numbers representing the lower and upper range of the bins. If not specified, it will use the min and max of x. |

## Value

A list of two tensors containing:

- A tensor representing the counts of elements in each bin.
- A tensor representing the bin edges.

## Examples

```
input_tensor <- random_uniform(8)
c(counts, edges) %<-% op_histogram(input_tensor)

counts

#> tf.Tensor([2. 1. 1. 1. 0. 1. 0. 0. 0. 2.], shape=(10), dtype=float32)

edges

#> tf.Tensor(
#> [0.01647806 0.10867032 0.20086257 0.29305482 0.38524708 0.47743934
#>  0.5696316  0.66182387 0.7540161  0.84620833 0.9384006 ], shape=(11), dtype=float32)
```

op_hstack *Stack tensors in sequence horizontally (column wise).*

---

## Description

This is equivalent to concatenation along the first axis for 1-D tensors, and along the second axis for all other tensors.

## Usage

```
op_hstack(xs, ...)
```

## Arguments

| | |
|---|---|
| xs, ... | list of tensors. |

## Value

The tensor formed by stacking the given tensors.

## See Also

op_identity *Return the identity tensor.*

## Description

The identity tensor is a square tensor with ones on the main diagonal and zeros elsewhere.

## Usage

```
op_identity(n, dtype = NULL)
```

## Arguments

| | |
|---|---|
| n | Number of rows (and columns) in the `n x n` output tensor. |
| dtype | Data type of the output tensor. |

## Value

The identity tensor.

op_ifft2 *Computes the 2D Inverse Fast Fourier Transform along the last two axes of*

## Description

input.

## Usage

```
op_ifft2(x)
```

## Arguments

| | |
|---|---|
| x | Tuple of the real and imaginary parts of the input tensor. Both tensors in the tuple should be of floating type. |

## Value

A tuple containing two tensors - the real and imaginary parts of the output.

## Examples

```
x <- list(op_array(rbind(c(1, 2), c(2, 1))),
          op_array(rbind(c(0, 1), c(1, 0))))
op_ifft2(x)

## [[1]]
## tf.Tensor(
## [[ 1.5  0. ]
##  [ 0.  -0.5]], shape=(2, 2), dtype=float64)
##
## [[2]]
## tf.Tensor(
## [[ 0.5 -0. ]
##  [-0.  -0.5]], shape=(2, 2), dtype=float64)
```

op_imag *Return the imaginary part of the complex argument.*

---

## Description

Return the imaginary part of the complex argument.

## Usage

```
op_imag(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

The imaginary component of the complex argument.

`op_image_affine_transform` *Applies the given transform(s) to the image(s).*

## Description

Applies the given transform(s) to the image(s).

## Usage

```
op_image_affine_transform(
  images,
  transform,
  interpolation = "bilinear",
  fill_mode = "constant",
  fill_value = 0L,
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| `images` | Input image or batch of images. Must be 3D or 4D. |
| `transform` | Projective transform matrix/matrices. A vector of length 8 or tensor of size N x 8. If one row of transform is `[a0, a1, a2, b0, b1, b2, c0, c1]`, then it maps the output point `(x, y)` to a transformed input point `(x', y') = ((a0 x + a1 y + a2) / k, (b0 x + b1 y` where `k = c0 x + c1 y + 1`. The transform is inverted compared to the transform mapping input points to output points. Note that gradients are not backpropagated into transformation parameters. Note that `c0` and `c1` are only effective when using TensorFlow backend and will be considered as `0` when using other backends. |
| `interpolation` | Interpolation method. Available methods are `"nearest"`, and `"bilinear"`. Defaults to `"bilinear"`. |
| `fill_mode` | Points outside the boundaries of the input are filled according to the given mode. Available methods are `"constant"`, `"nearest"`, `"wrap"` and `"reflect"`. Defaults to `"constant"`.<br>• `"reflect"`: `(d c b a \| a b c d \| d c b a)` The input is extended by reflecting about the edge of the last pixel.<br>• `"constant"`: `(k k k k \| a b c d \| k k k k)` The input is extended by filling all values beyond the edge with the same constant value k specified by `fill_value`.<br>• `"wrap"`: `(a b c d \| a b c d \| a b c d)` The input is extended by wrapping around to the opposite edge.<br>• `"nearest"`: `(a a a a \| a b c d \| d d d d)` The input is extended by the nearest pixel. |

| | |
|---|---|
| fill_value | Value used for points outside the boundaries of the input if fill_mode = "constant". Defaults to 0. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width).<br>If not specified, the value will default to config_image_data_format(). |

## Value

Applied affine transform image or batch of images.

## Examples

```
x <- random_uniform(c(2, 64, 80, 3)) # batch of 2 RGB images
transform <- op_array(rbind(c(1.5, 0, -20, 0, 1.5, -16, 0, 0),  # zoom
                            c(1, 0, -20, 0, 1, -16, 0, 0)))  # translation))
y <- op_image_affine_transform(x, transform)
shape(y)

## shape(2, 64, 80, 3)

# (2, 64, 80, 3)

x <- random_uniform(c(64, 80, 3)) # single RGB image
transform <- op_array(c(1.0, 0.5, -20, 0.5, 1.0, -16, 0, 0))  # shear
y <- op_image_affine_transform(x, transform)
shape(y)

## shape(64, 80, 3)

# (64, 80, 3)

x <- random_uniform(c(2, 3, 64, 80)) # batch of 2 RGB images
transform <- op_array(rbind(
  c(1.5, 0,-20, 0, 1.5,-16, 0, 0),  # zoom
  c(1, 0,-20, 0, 1,-16, 0, 0)  # translation
))
y <- op_image_affine_transform(x, transform, data_format = "channels_first")
shape(y)

## shape(2, 3, 64, 80)

# (2, 3, 64, 80)
```

---

op_image_crop *Crop* images *to a specified* height *and* width.

---

## Description

Crop images to a specified height and width.

## Usage

```
op_image_crop(
  images,
  top_cropping = NULL,
  left_cropping = NULL,
  bottom_cropping = NULL,
  right_cropping = NULL,
  target_height = NULL,
  target_width = NULL,
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| images | Input image or batch of images. Must be 3D or 4D. |
| top_cropping | Number of columns to crop from the top. |
| left_cropping | Number of columns to crop from the left. |
| bottom_cropping | Number of columns to crop from the bottom. |
| right_cropping | Number of columns to crop from the right. |
| target_height | Height of the output images. |
| target_width | Width of the output images. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format(). |

## Value

Cropped image or batch of images.

## Examples

```
images <- op_reshape(op_arange(1, 28, dtype="float32"), c(3, 3, 3))
images[, , 1] # print the first channel of the images

cropped_images <- op_image_crop(images, 0, 0, 2, 2)
cropped_images[, , 1] # print the first channel of the cropped images
```

op_image_elastic_transform
*Applies elastic deformation to the image(s).*

---

## Description

Apply random elastic deformation to 3D or 4D image tensors.

## Usage

```
op_image_elastic_transform(
  images,
  alpha = 20,
  sigma = 5,
  interpolation = "bilinear",
  fill_mode = "reflect",
  fill_value = 0,
  seed = NULL,
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| images | Input image or batch of images. Must be 3D or 4D. |
| alpha | Scaling factor that controls the intensity of the deformation. |
| sigma | Standard deviation of the Gaussian filter used for smoothing the displacement fields. |
| interpolation | Interpolation method. Available methods are "nearest", and "bilinear". Defaults to "bilinear". |
| fill_mode | Points outside the boundaries of the input are filled according to the given mode. Available methods are "constant", "nearest", "wrap" and "reflect". Defaults to "reflect".<br>• "reflect": (d c b a \| a b c d \| d c b a) The input is extended by reflecting about the edge of the last pixel.<br>• "constant": (k k k k \| a b c d \| k k k k) The input is extended by filling all values beyond the edge with the same constant value k specified by fill_value.<br>• "wrap": (a b c d \| a b c d \| a b c d) The input is extended by wrapping around to the opposite edge. |

- "nearest": (a a a a | a b c d | d d d d) The input is extended by the nearest pixel.

fill_value — Value used for points outside the boundaries of the input if fill_mode="constant". Defaults to 0.

seed — Optional integer seed for the random number generator.

data_format — A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to keras.config.image_data_format.

## Value

Transformed image or batch of images with elastic deformation.

## Examples

```
x <- random_uniform(c(2, 64, 80, 3))  # batch of 2 RGB images
y <- op_image_elastic_transform(x)
op_shape(y)
```

```
## shape(2, 64, 80, 3)
```

```
x <- random_uniform(c(64, 80, 3))  # single RGB image
y <- op_image_elastic_transform(x)
op_shape(y)
```

```
## shape(64, 80, 3)
```

```
x <- random_uniform(c(2, 3, 64, 80))  # batch of 2 RGB images
y <- op_image_elastic_transform(
  x,
  data_format = "channels_first",
  seed = 123
)
op_shape(y)
```

```
## shape(2, 3, 64, 80)
```

`op_image_extract_patches` *Extracts patches from the image(s).*

## Description

Extracts patches from the image(s).

## Usage

```
op_image_extract_patches(
  images,
  size,
  strides = NULL,
  dilation_rate = 1L,
  padding = "valid",
  data_format = "channels_last"
)
```

## Arguments

| | |
|---|---|
| `images` | Input image or batch of images. Must be 3D or 4D. |
| `size` | Patch size int or list (patch_height, patch_width) |
| `strides` | strides along height and width. If not specified, or if `NULL`, it defaults to the same value as `size`. |
| `dilation_rate` | This is the input stride, specifying how far two consecutive patch samples are in the input. For value other than 1, strides must be 1. NOTE: `strides` > 1 is not supported in conjunction with `dilation_rate` > 1 |
| `padding` | The type of padding algorithm to use: `"same"` or `"valid"`. |
| `data_format` | A string specifying the data format of the input tensor. It can be either `"channels_last"` or `"channels_first"`. `"channels_last"` corresponds to inputs with shape `(batch, height, width, channels)`, while `"channels_first"` corresponds to inputs with shape `(batch, channels, height, width)`. If not specified, the value will default to `config_image_data_format()`. |

## Value

Extracted patches 3D (if not batched) or 4D (if batched)

## Examples

```
image <- random_uniform(c(2, 20, 20, 3), dtype = "float32") # batch of 2 RGB images
patches <- op_image_extract_patches(image, c(5, 5))
shape(patches)
```

```
## shape(2, 4, 4, 75)

# (2, 4, 4, 75)
image <- random_uniform(c(20, 20, 3), dtype = "float32") # 1 RGB image
patches <- op_image_extract_patches(image, c(3, 3), c(1, 1))
shape(patches)

## shape(18, 18, 27)

# (18, 18, 27)
```

`op_image_gaussian_blur` *Applies a Gaussian blur to the image(s).*

---

## Description

Applies a Gaussian blur to the image(s).

## Usage

```
op_image_gaussian_blur(
  images,
  kernel_size = list(3L, 3L),
  sigma = list(1, 1),
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| images | Input image or batch of images. Must be 3D or 4D. |
| kernel_size | A tuple of two integers, specifying the height and width of the Gaussian kernel. |
| sigma | A tuple of two floats, specifying the standard deviation of the Gaussian kernel along height and width. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to keras.config.image_data_format. |

## Value

Blurred image or batch of images.

## Examples

```
x <- op_ones(c(2, 64, 80, 3))  # batch of 2 RGB images
y <- op_image_gaussian_blur(x)
op_shape(y)

## shape(2, 64, 80, 3)

x <- op_ones(c(64, 80, 3))  # single RGB image
y <- op_image_gaussian_blur(x)
op_shape(y)

## shape(64, 80, 3)

x <- op_ones(c(2, 3, 64, 80))  # batch of 2 RGB images, channels_first
y <- op_image_gaussian_blur(x, data_format = "channels_first")
op_shape(y)

## shape(2, 3, 64, 80)
```

---

`op_image_hsv_to_rgb` *Convert HSV images to RGB.*

---

## Description

`images` must be of float dtype, and the output is only well defined if the values in `images` are in `[0, 1]`.

## Usage

```
op_image_hsv_to_rgb(images, data_format = NULL)
```

## Arguments

| | |
|---|---|
| `images` | Input image or batch of images. Must be 3D or 4D. |
| `data_format` | A string specifying the data format of the input tensor. It can be either `"channels_last"` or `"channels_first"`. `"channels_last"` corresponds to inputs with shape `(batch, height, width, channels)`, while `"channels_first"` corresponds to inputs with shape `(batch, channels, height, width)`. If not specified, the value will default to `config_image_data_format()`. |

## Value

RGB image or batch of RGB images.

## Examples

```
x <- random_uniform(c(2, 4, 4, 3))
y <- op_image_hsv_to_rgb(x)
shape(y)

## shape(2, 4, 4, 3)

x <- random_uniform(c(4, 4, 3)) # Single HSV image
y <- op_image_hsv_to_rgb(x)
shape(y)

## shape(4, 4, 3)

x <- random_uniform(c(2, 3, 4, 4))
y <- op_image_hsv_to_rgb(x, data_format="channels_first")
shape(y)

## shape(2, 3, 4, 4)
```

---

`op_image_map_coordinates` *Map the input array to new coordinates by interpolation.*

---

## Description

Note that interpolation near boundaries differs from the scipy function, because we fixed an outstanding bug scipy/issues/2640.

## Usage

```
op_image_map_coordinates(
  inputs,
  coordinates,
  order,
  fill_mode = "constant",
  fill_value = 0L
)
```

## Arguments

| | |
|---|---|
| `inputs` | The input array. |
| `coordinates` | The coordinates at which `inputs` is evaluated. |
| `order` | The order of the spline interpolation. The order must be `0` or `1`. `0` indicates the nearest neighbor and `1` indicates the linear interpolation. |
| `fill_mode` | Points outside the boundaries of the inputs are filled according to the given mode. Available methods are `"constant"`, `"nearest"`, `"wrap"` and `"mirror"` and `"reflect"`. Defaults to `"constant"`.<br>• `"constant"`: `(k k k k \| a b c d \| k k k k)` inputs is extended by filling all values beyond the edge with the same constant value k specified by `fill_value`.<br>• `"nearest"`: `(a a a a \| a b c d \| d d d d)` inputs is extended by the nearest pixel.<br>• `"wrap"`: `(a b c d \| a b c d \| a b c d)` inputs is extended by wrapping around to the opposite edge.<br>• `"mirror"`: `(c d c b \| a b c d \| c b a b)` inputs is extended by mirroring about the edge.<br>• `"reflect"`: `(d c b a \| a b c d \| d c b a)` inputs is extended by reflecting about the edge of the last pixel. |
| `fill_value` | Value used for points outside the boundaries of the inputs if `fill_mode = "constant"`. Defaults to `0`. |

## Value

Output input or batch of inputs.

---

op_image_pad *Pad* images *with zeros to the specified* height *and* width.

---

## Description

Pad images with zeros to the specified height and width.

## Usage

```
op_image_pad(
  images,
  top_padding = NULL,
  left_padding = NULL,
  bottom_padding = NULL,
  right_padding = NULL,
  target_height = NULL,
  target_width = NULL,
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| images | Input image or batch of images. Must be 3D or 4D. |
| top_padding | Number of rows of zeros to add on top. |
| left_padding | Number of columns of zeros to add on the left. |
| bottom_padding | Number of rows of zeros to add at the bottom. |
| right_padding | Number of columns of zeros to add on the right. |
| target_height | Height of output images. |
| target_width | Width of output images. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format(). |

## Value

Padded image or batch of images.

## Examples

```
images <- random_uniform(c(15, 25, 3))
padded_images <- op_image_pad(
    images, 2, 3, target_height = 20, target_width = 30
)
shape(padded_images)

## shape(20, 30, 3)

batch_images <- random_uniform(c(2, 15, 25, 3))
padded_batch <- op_image_pad(batch_images, 2, 3,
                             target_height = 20,
                             target_width = 30)
shape(padded_batch)

## shape(2, 20, 30, 3)
```

`op_image_perspective_transform` *Applies a perspective transformation to the image(s).*

---

## Description

Applies a perspective transformation to the image(s).

## Usage

```
op_image_perspective_transform(
  images,
  start_points,
  end_points,
  interpolation = "bilinear",
  fill_value = 0L,
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| `images` | Input image or batch of images. Must be 3D or 4D. |
| `start_points` | A tensor of shape `(N, 4, 2)` or `(4, 2)`, representing the source points in the original image that define the transformation. |
| `end_points` | A tensor of shape `(N, 4, 2)` or `(4, 2)`, representing the target points in the output image after transformation. |
| `interpolation` | Interpolation method. Available methods are `"nearest"`, and `"bilinear"`. Defaults to `"bilinear"`. |

| | |
|---|---|
| fill_value | Value used for points outside the boundaries of the input if extrapolation is needed. Defaults to 0. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to keras.config.image_data_format. |

## Value

Applied perspective transform image or batch of images.

## Examples

```
# Batch of 2 RGB images (channels_last)
x <- op_ones(c(2, 64, 80, 3))
start_points <- op_stack(list(
  rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64)),
  rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64))
))
end_points <- op_stack(list(
  rbind(c(3, 5), c(7, 64), c(76, -10), c(84, 61)),
  rbind(c(8, 10), c(10, 61), c(65, 3), c(88, 43))
))
y <- op_image_perspective_transform(x, start_points, end_points)
op_shape(y)

## shape(2, 64, 80, 3)

# Single RGB image (channels_last)
x <- op_ones(c(64, 80, 3))
start_points <- rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64))
end_points <- rbind(c(3, 5), c(7, 64), c(76, -10), c(84, 61))
y <- op_image_perspective_transform(x, start_points, end_points)
op_shape(y)

## shape(64, 80, 3)

# Batch of 2 RGB images (channels_first)
x <- op_ones(c(2, 3, 64, 80))
start_points <- op_stack(list(
  rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64)),
  rbind(c(0, 0), c(0, 64), c(80, 0), c(80, 64))
))
end_points <- op_stack(list(
  rbind(c(3, 5), c(7, 64), c(76, -10), c(84, 61)),
```

```
  rbind(c(8, 10), c(10, 61), c(65, 3), c(88, 43))
))
y <- op_image_perspective_transform(
  x, start_points, end_points,
  data_format = "channels_first"
)
op_shape(y)

## shape(2, 3, 64, 80)
```

---

`op_image_resize` *Resize images to size using the specified interpolation method.*

---

## Description

Resize images to size using the specified interpolation method.

## Usage

```
op_image_resize(
  images,
```

```
  size,
  interpolation = "bilinear",
  antialias = FALSE,
  crop_to_aspect_ratio = FALSE,
  pad_to_aspect_ratio = FALSE,
  fill_mode = "constant",
  fill_value = 0,
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| images | Input image or batch of images. Must be 3D or 4D. |
| size | Size of output image in (height, width) format. |
| interpolation | Interpolation method. Available methods are "nearest", "bilinear", and "bicubic". Defaults to "bilinear". |
| antialias | Whether to use an antialiasing filter when downsampling an image. Defaults to FALSE. |
| crop_to_aspect_ratio | If TRUE, resize the images without aspect ratio distortion. When the original aspect ratio differs from the target aspect ratio, the output image will be cropped so as to return the largest possible window in the image (of size (height, width)) that matches the target aspect ratio. By default (crop_to_aspect_ratio=FALSE), aspect ratio may not be preserved. |
| pad_to_aspect_ratio | If TRUE, pad the images without aspect ratio distortion. When the original aspect ratio differs from the target aspect ratio, the output image will be evenly padded on the short side. |
| fill_mode | When using pad_to_aspect_ratio=TRUE, padded areas are filled according to the given mode. Only "constant" is supported at this time (fill with constant value, equal to fill_value). |
| fill_value | Float. Padding value to use when pad_to_aspect_ratio=TRUE. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format(). |

## Value

Resized image or batch of images.

## Examples

```
x <- random_uniform(c(2, 4, 4, 3)) # batch of 2 RGB images
y <- op_image_resize(x, c(2, 2))
shape(y)
```

```
## shape(2, 2, 2, 3)

x <- random_uniform(c(4, 4, 3)) # single RGB image
y <- op_image_resize(x, c(2, 2))
shape(y)

## shape(2, 2, 3)

x <- random_uniform(c(2, 3, 4, 4)) # batch of 2 RGB images
y <- op_image_resize(x, c(2, 2), data_format = "channels_first")
shape(y)

## shape(2, 3, 2, 2)
```

op_image_rgb_to_grayscale

*Convert RGB images to grayscale.*

---

## Description

This function converts RGB images to grayscale images. It supports both 3D and 4D tensors, where the last dimension represents channels.

## Usage

```
op_image_rgb_to_grayscale(images, data_format = NULL)
```

## Arguments

| | |
|---|---|
| images | Input image or batch of images. Must be 3D or 4D. |
| data_format | A string specifying the data format of the input tensor. It can be either "channels_last" or "channels_first". "channels_last" corresponds to inputs with shape (batch, height, width, channels), while "channels_first" corresponds to inputs with shape (batch, channels, height, width). If not specified, the value will default to config_image_data_format(). |

## Value

Grayscale image or batch of grayscale images.

## Examples

```
x <- random_uniform(c(2, 4, 4, 3))
y <- op_image_rgb_to_grayscale(x)
shape(y)
```

```
## shape(2, 4, 4, 1)
```

```
x <- random_uniform(c(4, 4, 3)) # Single RGB image
y = op_image_rgb_to_grayscale(x)
shape(y)
```

```
## shape(4, 4, 1)
```

```
x <- random_uniform(c(2, 3, 4, 4))
y <- op_image_rgb_to_grayscale(x, data_format="channels_first")
shape(y)
```

```
## shape(2, 1, 4, 4)
```

---

`op_image_rgb_to_hsv` *Convert RGB images to HSV.*

---

## Description

`images` must be of float dtype, and the output is only well defined if the values in `images` are in `[0, 1]`.

All HSV values are in `[0, 1]`. A hue of `0` corresponds to pure red, `1/3` is pure green, and `2/3` is pure blue.

## Usage

```
op_image_rgb_to_hsv(images, data_format = NULL)
```

## Arguments

| | |
|---|---|
| `images` | Input image or batch of images. Must be 3D or 4D. |
| `data_format` | A string specifying the data format of the input tensor. It can be either `"channels_last"` or `"channels_first"`. `"channels_last"` corresponds to inputs with shape `(batch, height, width, channels)`, while `"channels_first"` corresponds to inputs with shape `(batch, channels, height, width)`. If not specified, the value will default to `config_image_data_format()`. |

## Value

HSV image or batch of HSV images.

## Examples

```
x <- random_uniform(c(2, 4, 4, 3))
y <- op_image_rgb_to_hsv(x)
shape(y)

## shape(2, 4, 4, 3)

x <- random_uniform(c(4, 4, 3)) # Single RGB image
y <- op_image_rgb_to_hsv(x)
shape(y)

## shape(4, 4, 3)

x <- random_uniform(c(2, 3, 4, 4))
y <- op_image_rgb_to_hsv(x, data_format = "channels_first")
shape(y)

## shape(2, 3, 4, 4)
```

---

op_inner *Return the inner product of two tensors.*

---

## Description

Ordinary inner product of vectors for 1-D tensors (without complex conjugation), in higher dimensions a sum product over the last axes.

Multidimensional arrays are treated as vectors by flattening all but their last axes. The resulting dot product is performed over their last axes.

## Usage

```
op_inner(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. The last dimension of x1 and x2 must match. |

## Value

Output tensor. The shape of the output is determined by broadcasting the shapes of x1 and x2 after removing their last axes.

op_inv *Computes the inverse of a square tensor.*

---

## Description

Computes the inverse of a square tensor.

## Usage

```
op_inv(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor of shape (..., M, M). |

## Value

A tensor of shape (..., M, M) representing the inverse of x.

---

`op_in_top_k` *Checks if the targets are in the top-k predictions.*

---

## Description

Checks if the targets are in the top-k predictions.

## Usage

```
op_in_top_k(targets, predictions, k)
```

## Arguments

| | |
|---|---|
| `targets` | A tensor of true labels. |
| `predictions` | A tensor of predicted labels. |
| `k` | An integer representing the number of predictions to consider. |

## Value

A boolean tensor of the same shape as `targets`, where each element indicates whether the corresponding target is in the top-k predictions.

## Examples

```
targets <- op_array(c(2, 5, 3), "int32")
predictions <- op_array(dtype = "float32", rbind(
  c(0.1, 0.4, 0.6, 0.9, 0.5),
  c(0.1, 0.7, 0.9, 0.8, 0.3),
  c(0.1, 0.6, 0.9, 0.9, 0.5)
))
op_in_top_k(targets, predictions, k = 3L)

## tf.Tensor([ True False  True], shape=(3), dtype=bool)
```

`op_irfft` *Inverse real-valued Fast Fourier transform along the last axis.*

---

## Description

Computes the inverse 1D Discrete Fourier Transform of a real-valued signal over the inner-most dimension of input.

The inner-most dimension of the input is assumed to be the result of RFFT: the `fft_length / 2 + 1` unique components of the DFT of a real-valued signal. If `fft_length` is not provided, it is computed from the size of the inner-most dimension of the input (`fft_length = 2 * (inner - 1)`). If the FFT length used to compute is odd, it should be provided since it cannot be inferred properly.

Along the axis IRFFT is computed on, if `fft_length / 2 + 1` is smaller than the corresponding dimension of the input, the dimension is cropped. If it is larger, the dimension is padded with zeros.

## Usage

```
op_irfft(x, fft_length = NULL)
```

## Arguments

| | |
|---|---|
| x | List of the real and imaginary parts of the input tensor. Both tensors in the list should be of floating type. |
| fft_length | An integer representing the number of the fft length. If not specified, it is inferred from the length of the last axis of x. Defaults to NULL. |

## Value

A tensor containing the inverse real-valued Fast Fourier Transform along the last axis of x.

## Examples

```
real <- op_array(c(0, 1, 2, 3, 4))
imag <- op_array(c(0, 1, 2, 3, 4))
op_irfft(c(real, imag))

#> tf.Tensor(
#> [ 2.         -2.0606601   0.5        -0.35355338  0.          0.06066012
#>  -0.5         0.35355338], shape=(8), dtype=float32)

all.equal(op_irfft(op_rfft(real, 5), 5), real)

#> [1] "Mean relative difference: 5.960465e-08"
```

`op_isclose` *Return whether two tensors are element-wise almost equal.*

---

## Description

Return whether two tensors are element-wise almost equal.

## Usage

```
op_isclose(x1, x2, rtol = 1e-05, atol = 1e-08, equal_nan = FALSE)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |
| rtol | Relative tolerance. |
| atol | Absolute tolerance. |
| equal_nan | If TRUE, element-wise NaNs are considered equal. |

## Value

Output boolean tensor.

---

`op_isfinite` *Return whether a tensor is finite, element-wise.*

---

## Description

Real values are finite when they are not NaN, not positive infinity, and not negative infinity. Complex values are finite when both their real and imaginary parts are finite.

## Usage

```
op_isfinite(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output boolean tensor.

## See Also

`op_isnan` *Test element-wise for NaN and return result as a boolean tensor.*

---

## Description

Test element-wise for NaN and return result as a boolean tensor.

## Usage

```
op_isnan(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output boolean tensor.

---

`op_istft` *Inverse Short-Time Fourier Transform along the last axis of the input.*

---

## Description

To reconstruct an original waveform, the parameters should be the same in `stft`.

## Usage

```
op_istft(
  x,
  sequence_length,
  sequence_stride,
  fft_length,
  length = NULL,
  window = "hann",
```

```
  center = TRUE
)
```

## Arguments

| | |
|---|---|
| x | Tuple of the real and imaginary parts of the input tensor. Both tensors in the list should be of floating type. |
| sequence_length | An integer representing the sequence length. |
| sequence_stride | An integer representing the sequence hop size. |
| fft_length | An integer representing the size of the FFT that produced stft. Should be of type int32. |
| length | An integer representing the output is clipped to exactly length. If not specified, no padding or clipping take place. Defaults to NULL. |
| window | A string, a tensor of the window or NULL. If window is a string, available values are "hann" and "hamming". If window is a tensor, it will be used directly as the window and its length must be sequence_length. If window is NULL, no windowing is used. Defaults to "hann". |
| center | Whether x was padded on both sides so that the t-th sequence is centered at time t * sequence_stride. Defaults to TRUE. |

## Value

A tensor containing the inverse Short-Time Fourier Transform along the last axis of x.

## Examples

```
x <- op_convert_to_tensor(c(0, 1, 2, 3, 4))
op_istft(op_stft(x, 1, 1, 1), 1, 1, 1)

## tf.Tensor([], shape=(0), dtype=float64)

# array([0.0, 1.0, 2.0, 3.0, 4.0])
```

op_is_tensor *Check whether the given object is a tensor.*

---

## Description

Check whether the given object is a tensor.

## Usage

```
op_is_tensor(x)
```

## Arguments

| | |
|---|---|
| x | A variable. |

## Value

TRUE if x is a tensor, otherwise FALSE.

## Note

This checks for backend specific tensors so passing a TensorFlow tensor would return FALSE if your backend is PyTorch or JAX.

op_kaiser *Kaiser window function.*

## Description

The Kaiser window is defined as: `w[n] = I0(beta * sqrt(1 - (2 * n / (N - 1) - 1)^2)) / I0(beta)` where `I0` is the modified zeroth-order Bessel function of the first kind.

## Usage

```
op_kaiser(x, beta)
```

## Arguments

| | |
|---|---|
| `x` | Length of the window. Must be a positive integer. |
| `beta` | Shape parameter for the window. |

## Value

A 1D tensor containing the window values.

## Examples

```
op_kaiser(5, beta = 14)
```

```
## tf.Tensor([7.7268669e-06 1.6493215e-01 1.0000000e+00 1.6493215e-01 7.7268669e-06], shape=(5), dtype
```

`op_layer_normalization`

*Layer normalization (Ba et al., 2016).*

---

## Description

Normalizes activations in `x` for each example independently by centering to mean 0 and scaling to unit variance along the specified `axis`.

## Usage

```
op_layer_normalization(
  x,
  gamma = NULL,
  beta = NULL,
  axis = -1L,
  epsilon = NULL,
  ...
)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `gamma` | Optional scaling factor applied to the normalized output. |
| `beta` | Optional offset added to the normalized output. |
| `axis` | Axis or axes along which to compute statistics. Defaults to `-1`. |
| `epsilon` | Small constant added to the variance for numerical stability. |
| `...` | For forward/backward compatibility. |

## Value

Tensor with the same shape as `x` containing the normalized values.

## Examples

```
x <- op_arange(5, dtype = "float32")
op_layer_normalization(x)
```

```
## tf.Tensor([-1.4142134 -0.7071067  0.       0.7071068  1.4142137], shape=(5), dtype=float32)
```

`op_leaky_relu` *Leaky version of a Rectified Linear Unit activation function.*

---

## Description

It allows a small gradient when the unit is not active, it is defined as:
`f(x) = alpha * x for x < 0` or `f(x) = x for x >= 0`.

## Usage

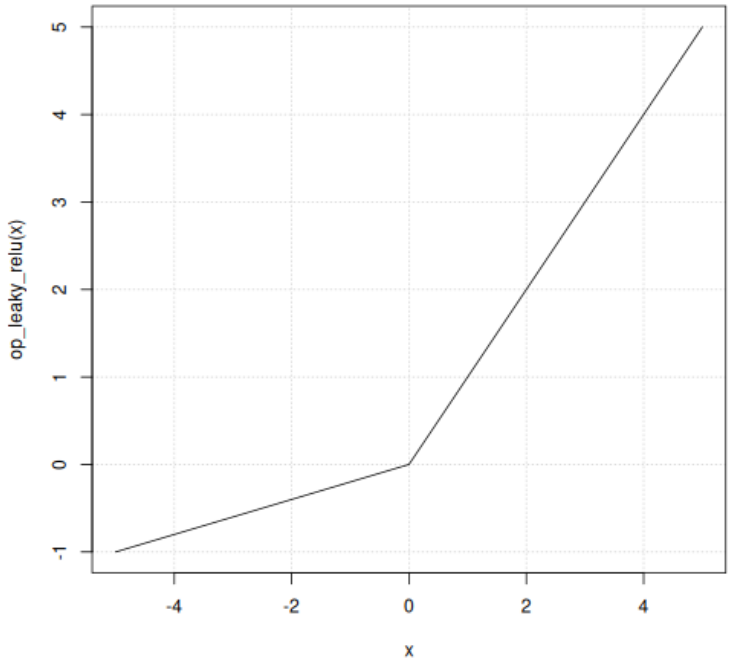
```
op_leaky_relu(x, negative_slope = 0.2)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `negative_slope` | Slope of the activation function at x < 0. Defaults to `0.2`. |

## Value

A tensor with the same shape as `x`.



## Examples

```
x <- op_array(c(-1., 0., 1.))
op_leaky_relu(x)
```

```
## tf.Tensor([-0.2  0.   1. ], shape=(3), dtype=float32)
```

```
# array([-0.2,  0. ,  1. ], shape=(3,), dtype=float64)
```

```
x <- seq(-5, 5, .1)
plot(x, op_leaky_relu(x),
     type = 'l', panel.first = grid())
```

---

`op_left_shift` *Shift the bits of an integer to the left.*

---

## Description

Bits are shifted to the left by appending `y` 0s at the right of `x`. Since the internal representation of numbers is in binary format, this operation is equivalent to multiplying `x` by `2^y`.

## Usage

```
op_left_shift(x, y)
```

## Arguments

| | |
|---|---|
| `x` | Input integer tensor. |
| `y` | Input integer tensor. |

## Value

Result tensor.

---

`op_less` *Return the truth value of* `x1 < x2` *element-wise.*

---

## Description

Note that this function is automatically called when using the R operator < with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_less(x, 2)

## tf.Tensor([ True False False False], shape=(4), dtype=bool)

x < 2

## tf.Tensor([ True False False False], shape=(4), dtype=bool)
```

## Usage

```
op_less(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise comparison of x1 and x2.

---

`op_less_equal` *Return the truth value of* `x1 <= x2` *element-wise.*

---

## Description

Note that this function is automatically called when using the R operator <= with a tensor.

```
(x <- op_arange(4))
```

```
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
```

```
op_less_equal(x, 2)
```

```
## tf.Tensor([ True  True False False], shape=(4), dtype=bool)

x <= 2

## tf.Tensor([ True  True False False], shape=(4), dtype=bool)
```

## Usage

```
op_less_equal(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise comparison of x1 and x2.

---

`op_linspace` *Return evenly spaced numbers over a specified interval.*

---

## Description

Returns `num` evenly spaced samples, calculated over the interval `[start, stop]`.

The endpoint of the interval can optionally be excluded.

## Usage

```
op_linspace(
  start,
  stop,
  num = 50L,
  endpoint = TRUE,
  retstep = FALSE,
  dtype = NULL,
  axis = 1L
)
```

## Arguments

| | |
|---|---|
| `start` | The starting value of the sequence. |
| `stop` | The end value of the sequence, unless `endpoint` is set to `FALSE`. In that case, the sequence consists of all but the last of `num + 1` evenly spaced samples, so that `stop` is excluded. Note that the step size changes when `endpoint` is `FALSE`. |
| `num` | Number of samples to generate. Defaults to `50`. Must be non-negative. |
| `endpoint` | If `TRUE`, `stop` is the last sample. Otherwise, it is not included. Defaults to `TRUE`. |
| `retstep` | If `TRUE`, return `(samples, step)`, where `step` is the spacing between samples. |
| `dtype` | The type of the output tensor. |
| `axis` | The axis in the result to store the samples. Relevant only if start or stop are array-like. Defaults to `1`, the first axis. |

## Value

A tensor of evenly spaced numbers. If `retstep` is `TRUE`, returns `(samples, step)`

## Note

Torch backend does not support `axis` argument.

op_log *Natural logarithm, element-wise.*

---

## Description

Natural logarithm, element-wise.

## Usage

```
op_log(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, element-wise natural logarithm of x.

## See Also

`op_log10` *Return the base 10 logarithm of the input tensor, element-wise.*

---

## Description

Return the base 10 logarithm of the input tensor, element-wise.

## Usage

```
op_log10(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, element-wise base 10 logarithm of `x`.

op_log1p *Returns the natural logarithm of one plus the* x*, element-wise.*

---

## Description

Calculates log(1 + x).

## Usage

```
op_log1p(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, element-wise natural logarithm of 1 + x.

op_log2 *Base-2 logarithm of* x*, element-wise.*

---

## Description

Base-2 logarithm of x, element-wise.

## Usage

```
op_log2(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, element-wise base-2 logarithm of x.

## See Also

op_logaddexp *Logarithm of the sum of exponentiations of the inputs.*

## Description

Calculates `log(exp(x1) + exp(x2))`.

## Usage

```
op_logaddexp(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | Input tensor. |
| x2 | Input tensor. |

## Value

Output tensor, element-wise logarithm of the sum of exponentiations of the inputs.

## See Also

- https://keras.io/api/ops/numpy#logaddexp-function

`op_logdet` *Computes log of the determinant of a hermitian positive definite matrix.*

---

## Description

Computes log of the determinant of a hermitian positive definite matrix.

## Usage

```
op_logdet(x)
```

## Arguments

| | |
|---|---|
| x | Input matrix. It must 2D and square. |

## Value

The natural log of the determinant of matrix.

## See Also

---

`op_logical_and` *Computes the element-wise logical AND of the given input tensors.*

---

## Description

Zeros are treated as `FALSE` and non-zeros are treated as `TRUE`.

## Usage

```
op_logical_and(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | Input tensor. |
| x2 | Input tensor. |

## Details

Note that this function is automatically called when using the R operator & with a tensor.

## Value

Output tensor, element-wise logical AND of the inputs.

`op_logical_not` *Computes the element-wise NOT of the given input tensor.*

---

## Description

Zeros are treated as `FALSE` and non-zeros are treated as `TRUE`.

Note that this function is automatically called when using the R operator `!` with a tensor.

## Usage

```
op_logical_not(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, element-wise logical NOT of the input.

---

`op_logical_or` *Computes the element-wise logical OR of the given input tensors.*

---

## Description

Zeros are treated as `FALSE` and non-zeros are treated as `TRUE`.

Note that this function is automatically called when using the R operator `|` with a tensor.

## Usage

```
op_logical_or(x1, x2)
```

## Arguments

| | |
|---|---|
| `x1` | Input tensor. |
| `x2` | Input tensor. |

## Value

Output tensor, element-wise logical OR of the inputs.

`op_logical_xor` *Compute the truth value of* `x1 XOR x2`*, element-wise.*

---

## Description

Compute the truth value of `x1 XOR x2`, element-wise.

## Usage

```
op_logical_xor(x1, x2)
```

## Arguments

| | |
|---|---|
| `x1` | First input tensor. |
| `x2` | Second input tensor. |

## Value

Output boolean tensor.

---

`op_logspace` *Returns numbers spaced evenly on a log scale.*

---

## Description

In linear space, the sequence starts at `base ** start` and ends with `base ** stop` (see `endpoint` below).

## Usage

```
op_logspace(
  start,
  stop,
  num = 50L,
  endpoint = TRUE,
  base = 10L,
  dtype = NULL,
  axis = 1L
)
```

## Arguments

| | |
|---|---|
| `start` | The starting value of the sequence. |
| `stop` | The final value of the sequence, unless `endpoint` is `FALSE`. In that case, `num + 1` values are spaced over the interval in log-space, of which all but the last (a sequence of length `num`) are returned. |

| | |
|---|---|
| num | Number of samples to generate. Defaults to 50. |
| endpoint | If TRUE, stop is the last sample. Otherwise, it is not included. Defaults to TRUE. |
| base | The base of the log space. Defaults to 10. |
| dtype | The type of the output tensor. |
| axis | The axis in the result to store the samples. Relevant only if start or stop are array-like. |

## Value

A tensor of evenly spaced samples on a log scale.

## Note

Torch backend does not support axis argument.

`op_logsumexp` *Computes the logarithm of sum of exponentials of elements in a tensor.*

---

## Description

Computes the logarithm of sum of exponentials of elements in a tensor.

## Usage

```
op_logsumexp(x, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | An integer or a list of integers specifying the axis/axes along which to compute the sum. If NULL, the sum is computed over all elements. Defaults to NULL. |
| keepdims | A boolean indicating whether to keep the dimensions of the input tensor when computing the sum. Defaults to FALSE. |

## Value

A tensor containing the logarithm of the sum of exponentials of elements in x.

## Examples

```
x <- op_convert_to_tensor(c(1, 2, 3))
op_logsumexp(x)

## tf.Tensor(3.4076059644443806, shape=(), dtype=float64)
```

`op_log_sigmoid` *Logarithm of the sigmoid activation function.*

---

## Description

It is defined as `f(x) = log(1 / (1 + exp(-x)))`.

## Usage

```
op_log_sigmoid(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A tensor with the same shape as x.

## Examples

```
x <- op_convert_to_tensor(c(-0.541391, 0.0, 0.50, 5.0))
op_log_sigmoid(x)
```

```
## tf.Tensor([-1.00004181 -0.69314718 -0.47407698 -0.00671535], shape=(4), dtype=float64)
```

`op_log_softmax` *Log-softmax activation function.*

---

## Description

It is defined as: `f(x) = x - max(x) - log(sum(exp(x - max(x))))`

## Usage

```
op_log_softmax(x, axis = -1L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Integer, axis along which the log-softmax is applied. Defaults to `-1`. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1., 0., 1.))
op_log_softmax(x)
```

```
## tf.Tensor([-2.407606   -1.4076059  -0.40760595], shape=(3), dtype=float32)
```

---

`op_lstsq` *Return the least-squares solution to a linear matrix equation.*

---

## Description

Computes the vector x that approximately solves the equation a %*% x = b. The equation may be under-, well-, or over-determined (i.e., the number of linearly independent rows of a can be less than, equal to, or greater than its number of linearly independent columns). If a is square and of full rank, then x (but for round-off error) is the exact solution of the equation. Else, x minimizes the L2 norm of b - a %*% x.

If there are multiple minimizing solutions, the one with the smallest L2 norm is returned.

## Usage

```
op_lstsq(a, b, rcond = NULL)
```

## Arguments

| | |
|---|---|
| a | "Coefficient" matrix of shape (M, N). |
| b | Ordinate or "dependent variable" values, of shape (M) or (M, K). If b is two-dimensional, the least-squares solution is calculated for each of the K columns of b. |
| rcond | Cut-off ratio for small singular values of a. For the purposes of rank determination, singular values are treated as zero if they are smaller than rcond times the largest singular value of a. |

## Value

Tensor with shape (N) or (N, K) containing the least-squares solutions.

**NOTE:** The output differs from numpy.linalg.lstsq(). NumPy returns a tuple with four elements, the first of which being the least-squares solutions and the others being essentially never used. Keras only returns the first value. This is done both to ensure consistency across backends (which cannot be achieved for the other values) and to simplify the API.

op_lu_factor *Computes the lower-upper decomposition of a square matrix.*

---

## Description

Computes the lower-upper decomposition of a square matrix.

## Usage

```
op_lu_factor(x)
```

## Arguments

| | |
|---|---|
| x | A tensor of shape (..., M, M). |

## Value

A tuple of two tensors: a tensor of shape (..., M, M) containing the lower and upper triangular matrices and a tensor of shape (..., M) containing the pivots.

op_map *Map a function over leading array axes.*

---

## Description

Like purrr::map() or base::lapply(), except inputs and outputs are in the form of stacked arrays. Consider using the op_vectorized_map() transform instead, unless you need to apply a function element by element for reduced memory usage or heterogeneous computation with other control flow primitives.

When xs is an array type, the semantics of op_map() match this implementation:

```
op_map <- function(xs, f) {
  xs |>
    op_unstack() |>
    lapply(f) |>
    op_stack()
}
```

## Usage

```
op_map(xs, f)
```

## Arguments

| | |
|---|---|
| xs | Values over which to map along the leading axis. |
| f | Callable defines the function to apply element-wise over the first axis or axes of xs. |

## Value

Mapped values.

## Examples

```
f <- function(x) x^2
xs <- op_arange(10)
ys <- op_map(xs, f)
ys
```

```
## tf.Tensor([ 1.  4.  9. 16. 25. 36. 49. 64. 81. 100.], shape=(10), dtype=float32)
```

```
f <- function(x) list(y1 = x^2, y2 = x * 10)  # Can have nested outputs
ys <- op_map(xs, f)
ys$y1
```

```
## tf.Tensor([ 1.  4.  9. 16. 25. 36. 49. 64. 81. 100.], shape=(10), dtype=float32)
```

```
ys$y2
```

```
## tf.Tensor([ 10.  20.  30.  40.  50.  60.  70.  80.  90. 100.], shape=(10), dtype=float32)
```

`op_matmul` *Matrix product of two tensors.*

---

## Description

- If both tensors are 1-dimensional, the dot product (scalar) is returned.
- If either tensor is N-D, N > 2, it is treated as a stack of matrices residing in the last two indexes and broadcast accordingly.
- If the first tensor is 1-D, it is promoted to a matrix by prepending a 1 to its dimensions. After matrix multiplication the prepended 1 is removed.
- If the second tensor is 1-D, it is promoted to a matrix by appending a 1 to its dimensions. After matrix multiplication the appended 1 is removed.

## Usage

```
op_matmul(x1, x2)
```

## Arguments

| | |
|---|---|
| `x1` | First tensor. |
| `x2` | Second tensor. |

## Value

Output tensor, matrix product of the inputs.

---

op_max *Return the maximum of a tensor or maximum along an axis.*

---

## Description

Return the maximum of a tensor or maximum along an axis.

## Usage

```
op_max(x, axis = NULL, keepdims = FALSE, initial = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis or axes along which to operate. By default, flattened input is used. |
| keepdims | If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. Defaults to FALSE. |
| initial | The minimum value of an output element. Defaults to NULL. |

## Value

Maximum of x.

## Examples

```
(x <- op_convert_to_tensor(rbind(c(1, 3, 5), c(1, 5, 2))))

## tf.Tensor(
## [[1. 3. 5.]
##  [1. 5. 2.]], shape=(2, 3), dtype=float64)

op_max(x)

## tf.Tensor(5.0, shape=(), dtype=float64)

op_max(x, axis = 1)

## tf.Tensor([1. 5. 5.], shape=(3), dtype=float64)

op_max(x, axis = 1, keepdims = TRUE)

## tf.Tensor([[1. 5. 5.]], shape=(1, 3), dtype=float64)
```

op_maximum *Element-wise maximum of* x1 *and* x2.

## Description

Element-wise maximum of x1 and x2.

## Usage

```
op_maximum(x1, x2)

op_pmax(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First tensor. |
| x2 | Second tensor. |

## Value

Output tensor, element-wise maximum of x1 and x2.

op_max_pool *Max pooling operation.*

## Description

Max pooling operation.

## Usage

```
op_max_pool(
  inputs,
  pool_size,
  strides = NULL,
  padding = "valid",
  data_format = NULL
)
```

## Arguments

| | |
|---|---|
| inputs | Tensor of rank N+2. inputs has shape (batch_size,) + inputs_spatial_shape + (num_channels,) if data_format = "channels_last", or (batch_size, num_channels) + inputs_spatial_shape if data_format = "channels_first". Pooling happens over the spatial dimensions only. |
| pool_size | int or tuple/list of integers of size len(inputs_spatial_shape), specifying the size of the pooling window for each spatial dimension of the input tensor. If pool_size is int, then every spatial dimension shares the same pool_size. |
| strides | int or tuple/list of integers of size len(inputs_spatial_shape). The stride of the sliding window for each spatial dimension of the input tensor. If strides is int, then every spatial dimension shares the same strides. |
| padding | string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides = 1. |
| data_format | A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format = "channels_last", inputs is of shape (batch_size, ..., channels) while if data_format = "channels_first", inputs is of shape (batch_size, channels, ...). |

## Value

A tensor of rank N+2, the result of the max pooling operation.

op_mean *Compute the arithmetic mean along the specified axes.*

---

## Description

Compute the arithmetic mean along the specified axes.

## Usage

```
op_mean(x, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis or axes along which the means are computed. The default is to compute the mean of the flattened tensor. |
| keepdims | If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. |

## Value

Output tensor containing the mean values.

## See Also

## op_median *Compute the median along the specified axis.*

---

## Description

Compute the median along the specified axis.

## Usage

```
op_median(x, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis or axes along which the medians are computed. Defaults to axis = NULL which is to compute the median(s) along a flattened version of the array. |
| keepdims | If this is set to TRUE, the axes which are reduce are left in the result as dimensions with size one. |

## Value

The output tensor.

---

op_meshgrid *Creates grids of coordinates from coordinate vectors.*

---

## Description

Given N 1-D tensors T0, T1, ..., TN-1 as inputs with corresponding lengths S0, S1, ..., SN-1, this creates an N N-dimensional tensors G0, G1, ..., GN-1 each with shape (S0, ..., SN-1) where the output Gi is constructed by expanding Ti to the result shape.

## Usage

```
op_meshgrid(..., indexing = "xy")
```

## Arguments

| | |
|---|---|
| ... | 1-D tensors representing the coordinates of a grid. |
| indexing | "xy" or "ij". "xy" is cartesian; "ij" is matrix indexing of output. Defaults to "xy". |

## Value

Sequence of N tensors.

## Examples

```
x <- op_array(c(1, 2, 3), "int32")
y <- op_array(c(4, 5, 6), "int32")

c(grid_x, grid_y) %<-% op_meshgrid(x, y, indexing = "ij")
grid_x

## tf.Tensor(
## [[1 1 1]
##  [2 2 2]
##  [3 3 3]], shape=(3, 3), dtype=int32)

# array([[1, 1, 1],
#        [2, 2, 2],
#        [3, 3, 3]))
grid_y

## tf.Tensor(
## [[4 5 6]
##  [4 5 6]
##  [4 5 6]], shape=(3, 3), dtype=int32)

# array([[4, 5, 6],
#        [4, 5, 6],
#        [4, 5, 6]))
```

---

`op_min` *Return the minimum of a tensor or minimum along an axis.*

---

## Description

Return the minimum of a tensor or minimum along an axis.

## Usage

```
op_min(x, axis = NULL, keepdims = FALSE, initial = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Axis or axes along which to operate. By default, flattened input is used. |
| `keepdims` | If this is set to `TRUE`, the axes which are reduced are left in the result as dimensions with size one. Defaults to `FALSE`. |
| `initial` | The maximum value of an output element. Defaults to `NULL`. |

## Value

Minimum of `x`.

## Examples

```
(x <- op_convert_to_tensor(rbind(c(1, 3, 5), c(1, 5, 2))))

## tf.Tensor(
## [[1. 3. 5.]
##  [1. 5. 2.]], shape=(2, 3), dtype=float64)

op_min(x)

## tf.Tensor(1.0, shape=(), dtype=float64)

op_min(x, axis = 1)

## tf.Tensor([1. 3. 2.], shape=(3), dtype=float64)

op_min(x, axis = 1, keepdims = TRUE)

## tf.Tensor([[1. 3. 2.]], shape=(1, 3), dtype=float64)
```

op_minimum *Element-wise minimum of* x1 *and* x2.

## Description

Element-wise minimum of x1 and x2.

## Usage

```
op_minimum(x1, x2)

op_pmin(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First tensor. |
| x2 | Second tensor. |

## Value

Output tensor, element-wise minimum of x1 and x2.

## See Also

op_mod *Returns the element-wise remainder of division.*

## Description

Note that this function is automatically called when using the R operator `%%` with a tensor.

```
(x <- op_arange(10))
```

```
## tf.Tensor([ 1.  2.  3.  4.  5.  6.  7.  8.  9. 10.], shape=(10), dtype=float32)
```

```
op_mod(x, 3)
```

```
## tf.Tensor([1. 2. 0. 1. 2. 0. 1. 2. 0. 1.], shape=(10), dtype=float32)
```

```
x %% 3
```

```
## tf.Tensor([1. 2. 0. 1. 2. 0. 1. 2. 0. 1.], shape=(10), dtype=float32)
```

## Usage

```
op_mod(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First tensor. |
| x2 | Second tensor. |

## Value

Output tensor, element-wise remainder of division.

---

op_moments *Calculates the mean and variance of* x.

---

## Description

The mean and variance are calculated by aggregating the contents of x across axes. If x is 1-D and axes = c(1) this is just the mean and variance of a vector.

## Usage

```
op_moments(x, axes, keepdims = FALSE, synchronized = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axes | A list of axes which to compute mean and variance. |
| keepdims | If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. |
| synchronized | Only applicable with the TensorFlow backend. If TRUE, synchronizes the global batch statistics (mean and variance) across all devices at each training step in a distributed training strategy. If FALSE, each replica uses its own local batch statistics. |

## Value

A list containing two tensors - mean and variance.

## Examples

```
x <- op_convert_to_tensor(c(0, 1, 2, 3, 100), dtype = "float32")
op_moments(x, axes = c(1))
```

```
## [[1]]
## tf.Tensor(21.2, shape=(), dtype=float32)
##
## [[2]]
## tf.Tensor(1553.3601, shape=(), dtype=float32)
```

op_moveaxis *Move axes of a tensor to new positions.*

## Description

Other axes remain in their original order.

## Usage

```
op_moveaxis(x, source, destination)
```

## Arguments

| | |
|---|---|
| x | Tensor whose axes should be reordered. |
| source | Original positions of the axes to move. These must be unique. |
| destination | Destinations positions for each of the original axes. These must also be unique. |

## Value

Tensor with moved axes.

op_multiply *Multiply arguments element-wise.*

## Description

Note that this function is automatically called when using the R operator `*` with a tensor.

```
(x <- op_arange(4))
```

```
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
```

```
op_multiply(x, x)
```

```
## tf.Tensor([ 1.  4.  9. 16.], shape=(4), dtype=float32)
```

```
x * x
```

```
## tf.Tensor([ 1.  4.  9. 16.], shape=(4), dtype=float32)
```

## Usage

```
op_multiply(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise product of `x1` and `x2`.

`op_multi_hot` *Encodes integer labels as multi-hot vectors.*

---

## Description

This function encodes integer labels as multi-hot vectors, where each label is mapped to a binary value in the resulting vector.

## Usage

```
op_multi_hot(
  inputs,
  num_classes,
  axis = -1L,
  dtype = NULL,
  sparse = FALSE,
  ...
)
```

## Arguments

| | |
|---|---|
| `inputs` | Tensor of integer labels to be converted to multi-hot vectors. |
| `num_classes` | Integer, the total number of unique classes. |
| `axis` | (optional) Axis along which the multi-hot encoding should be added. Defaults to `-1`, which corresponds to the last dimension. |
| `dtype` | (optional) The data type of the resulting tensor. Default is backend's float type. |
| `sparse` | Whether to return a sparse tensor; for backends that support sparse tensors. |
| `...` | For forward/backwards compatability |

## Value

Tensor: The multi-hot encoded tensor.

## Examples

```
data <- op_convert_to_tensor(c(0, 4))
op_multi_hot(data, num_classes = 5)
```

```
## tf.Tensor([1. 0. 0. 0. 1.], shape=(5), dtype=float32)
```

op_nan_to_num *Replace NaN with zero and infinity with large finite numbers.*

---

## Description

Replace NaN with zero and infinity with large finite numbers.

## Usage

```
op_nan_to_num(x, nan = 0, posinf = NULL, neginf = NULL)
```

## Arguments

| | |
|---|---|
| x | Input data. |
| nan | Optional float or int. Value to replace NaN entries with. |
| posinf | Optional float or int. Value to replace positive infinity with. |
| neginf | Optional float or int. Value to replace negative infinity with. |

## Value

x, with non-finite values replaced.

## Example

```
(x <- op_convert_to_tensor(c(1, NaN, -Inf, Inf)))

## tf.Tensor([  1.  nan -inf  inf], shape=(4), dtype=float64)

op_nan_to_num(x)

## tf.Tensor([ 1.00000000e+000  0.00000000e+000 -1.79769313e+308  1.79769313e+308], shape=(4), dtype=f

op_nan_to_num(x, nan = -1, posinf = 2, neginf = -2)

## tf.Tensor([ 1. -1. -2.  2.], shape=(4), dtype=float64)
```

op_ndim *Return the number of dimensions of a tensor.*

---

## Description

Return the number of dimensions of a tensor.

## Usage

```
op_ndim(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

The number of dimensions in x.

---

op_negative *Numerical negative, element-wise.*

---

## Description

Note that this function is automatically called when using the unary R operator - with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_negative(x)

## tf.Tensor([-1. -2. -3. -4.], shape=(4), dtype=float32)

-x

## tf.Tensor([-1. -2. -3. -4.], shape=(4), dtype=float32)
```

## Usage

```
op_negative(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, `y = -x`.

---

op_nonzero *Return the indices of the elements that are non-zero.*

---

## Description

Return the indices of the elements that are non-zero.

## Usage

```
op_nonzero(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Details

**Example:**

op_nonzero() indices can be used with <tensor>@r[

```
(x <- op_scatter(indices = rbind(1, 5, 10), values = c(1, 2, 3), shape = c(10)))
```

```
## tf.Tensor([1. 0. 0. 0. 2. 0. 0. 0. 0. 3.], shape=(10), dtype=float64)

(nz <- op_nonzero(x))

## tf.Tensor(
## [[ 1]
##  [ 5]
##  [10]], shape=(3, 1), dtype=int32)

x@r[nz]

## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)

# same as `x@r[nz]`
x@r[x != 0]

## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)

x@r[op_cast(x, "bool")]

## tf.Tensor([1. 2. 3.], shape=(3), dtype=float64)

# 2d example
(x2 <- op_stack(c(x, op_roll(x, 1), op_roll(x, 2))))

## tf.Tensor(
## [[1. 0. 0. 0. 2. 0. 0. 0. 0. 3.]
##  [3. 1. 0. 0. 0. 2. 0. 0. 0. 0.]
##  [0. 3. 1. 0. 0. 0. 2. 0. 0. 0.]], shape=(3, 10), dtype=float64)

x2@r[op_nonzero(x2)]

## tf.Tensor([1. 2. 3. 3. 1. 2. 3. 1. 2.], shape=(9), dtype=float64)

x3 <- op_stack(c(x2, x2*1.1))
x3@r[op_nonzero(x3)]

## tf.Tensor([1.  2.  3.  3.  1.  2.  3.  1.  2.  1.1 2.2 3.3 3.3 1.1 2.2 3.3 1.1 2.2], shape=(18), dtype=f
```

## Value

Indices of elements that are non-zero.

`op_norm` *Matrix or vector norm.*

---

## Description

This function is able to return one of eight different matrix norms, or one of an infinite number of vector norms (described below), depending on the value of the `ord` parameter.

## Usage

```
op_norm(x, ord = NULL, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `ord` | Order of the norm (see table under Notes). The default is `NULL`. |
| `axis` | If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a length 2 vector, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. |
| `keepdims` | If this is set to `TRUE`, the axes which are reduced are left in the result as dimensions with size one. |

## Value

Norm of the matrix or vector(s).

## Note

For values of `ord < 1`, the result is, strictly speaking, not a mathematical 'norm', but it may still be useful for various numerical purposes. The following norms can be calculated:

- For matrices:
  - `ord=NULL`: Frobenius norm
  - `ord="fro"`: Frobenius norm
  - `ord="nuc"`: nuclear norm
  - `ord=Inf`: `max(sum(abs(x), axis=2))`
  - `ord=-Inf`: `min(sum(abs(x), axis=2))`
  - `ord=0`: not supported
  - `ord=1`: `max(sum(abs(x), axis=1))`
  - `ord=-1`: `min(sum(abs(x), axis=1))`
  - `ord=2`: 2-norm (largest sing. value)
  - `ord=-2`: smallest singular value
  - other: not supported
- For vectors:
  - `ord=NULL`: 2-norm
  - `ord="fro"`: not supported
  - `ord="nuc"`: not supported
  - `ord=Inf`: `max(abs(x))`
  - `ord=-Inf`: `min(abs(x))`
  - `ord=0`: `sum(x != 0)`
  - `ord=1`: as below
  - `ord=-1`: as below
  - `ord=2`: as below
  - `ord=-2`: as below
  - other: `sum(abs(x)^ord)^(1/ord)`

## Examples

```
x <- op_reshape(op_arange(9, dtype="float32") - 4, c(3, 3))
op_norm(x)

## tf.Tensor(8.306623, shape=(), dtype=float32)

# 7.7459664
```

---

`op_normalize` *Normalizes* `x` *over the specified axis.*

---

## Description

It is defined as: `op_normalize(x) = x / max(norm(x), epsilon)`.

## Usage

```
op_normalize(x, axis = -1L, order = 2L, epsilon = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | The axis or axes along which to perform normalization. Default to -1. |
| `order` | The exponent value in the norm formulation. Defaults to 2. |
| `epsilon` | A lower bound value for the norm. Defaults to `config_epsilon()`. |

## Value

The normalized array.

## Examples

```
x <- op_convert_to_tensor(rbind(c(1, 2, 3), c(4, 5, 6)))
x_norm <- op_normalize(x)
x_norm

## tf.Tensor(
## [[0.26726124 0.53452248 0.80178373]
##  [0.45584231 0.56980288 0.68376346]], shape=(2, 3), dtype=float64)
```

---

`op_not_equal` *Return* `(x1 != x2)` *element-wise.*

---

## Description

Note that this function is automatically called when using the R operator `!=` with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_not_equal(x, 2)

## tf.Tensor([ True False  True  True], shape=(4), dtype=bool)

x != 2

## tf.Tensor([ True False  True  True], shape=(4), dtype=bool)
```

## Usage

```
op_not_equal(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise comparison of `x1` and `x2`.

op_ones *Return a new tensor of given shape and type, filled with ones.*

---

## Description

Return a new tensor of given shape and type, filled with ones.

## Usage

```
op_ones(shape, dtype = NULL)
```

## Arguments

| | |
|---|---|
| shape | Shape of the new tensor. |
| dtype | Desired data type of the tensor. |

## Value

Tensor of ones with the given shape and dtype.

op_ones_like *Return a tensor of ones with the same shape and type of* x.

---

## Description

Return a tensor of ones with the same shape and type of x.

## Usage

```
op_ones_like(x, dtype = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| dtype | Overrides the data type of the result. |

## Value

A tensor of ones with the same shape and type as x.

op_one_hot *Converts integer tensor* x *into a one-hot tensor.*

## Description

The one-hot encoding is a representation where each integer value is converted into a binary vector with a length equal to num_classes, and the index corresponding to the integer value is marked as 1, while all other indices are marked as 0.

## Usage

```
op_one_hot(
  x,
  num_classes,
  axis = -1L,
  dtype = NULL,
  sparse = FALSE,
  zero_indexed = FALSE
)
```

## Arguments

| | |
|---|---|
| x | Integer tensor to be encoded. The shape can be arbitrary, but the dtype should be integer. R factors are coerced to integer. |
| num_classes | Number of classes for the one-hot encoding. If x is a factor and num_classes is NULL or missing, then levels(x) is used. |
| axis | Axis along which the encoding is performed. -1 represents the last axis. Defaults to -1. |
| dtype | (Optional) Data type of the output tensor. If not provided, it defaults to the default data type of the backend. |
| sparse | Whether to return a sparse tensor; for backends that support sparse tensors. |
| zero_indexed | If TRUE, treats indices as zero-based (0 encodes to first position); if FALSE (default), treats indices as one-based (1 encodes to first position). |

## Value

Integer tensor: One-hot encoded tensor with the same shape as x except for the specified axis dimension, which will have a length of num_classes. The dtype of the output tensor is determined by dtype or the default data type of the backend.

## Examples

```
x <- op_array(c(2, 4, 3, 1), "int32")
op_one_hot(x, num_classes = 4)
```

```
## tf.Tensor(
## [[0. 1. 0. 0.]
##  [0. 0. 0. 1.]
##  [0. 0. 1. 0.]
##  [1. 0. 0. 0.]], shape=(4, 4), dtype=float32)
```

```
op_one_hot(x - 1, num_classes = 4, zero_indexed = TRUE)
```

```
## tf.Tensor(
## [[0. 1. 0. 0.]
##  [0. 0. 0. 1.]
##  [0. 0. 1. 0.]
##  [1. 0. 0. 0.]], shape=(4, 4), dtype=float32)
```

op_outer *Compute the outer product of two vectors.*

---

## Description

Given two vectors x1 and x2, the outer product is:

```
out[i, j] = x1[i] * x2[j]
```

## Usage

```
op_outer(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Outer product of x1 and x2.

op_pad *Pad a tensor.*

---

## Description

Pad a tensor.

## Usage

```
op_pad(x, pad_width, mode = "constant", constant_values = NULL)
```

## Arguments

| | |
|---|---|
| x | Tensor to pad. |
| pad_width | Number of values padded to the edges of each axis. `((before_1, after_1), ...(before_N, after_N)` unique pad widths for each axis. `((before, after),)` yields same before and after pad for each axis. `(pad,)` or `int` is a shortcut for `before = after = pad` width for all axes. |
| mode | One of `"constant"`, `"edge"`, `"linear_ramp"`, `"maximum"`, `"mean"`, `"median"`, `"minimum"`, `"reflect"`, `"symmetric"`, `"wrap"`, `"empty"`, `"circular"`. Defaults to `"constant"`. |
| constant_values | Value to pad with if `mode == "constant"`. Defaults to `0`. A `ValueError` is raised if not `NULL` and `mode != "constant"`. |

## Value

Padded tensor.

## Note

Torch backend only supports modes `"constant"`, `"reflect"`, `"symmetric"` and `"circular"`. Only Torch backend supports `"circular"` mode.

Note: Tensorflow backend only supports modes `"constant"`, `"reflect"` and `"symmetric"`.

---

`op_polar` *Constructs a complex tensor whose elements are Cartesian*

---

## Description

coordinates corresponding to the polar coordinates with absolute value `abs` and angle `angle`.

The operation is numerically equivalent to `torch.polar()`. It is not equivalent to `scipy.lingalg.polar()` which performs Singular Value Decomposition.

Given the magnitude (`abs_`) and angle (`angle`), this function computes the corresponding complex number in the form of `real + imaginary * 1i`, where:

- `real = abs_ * cos(angle)`
- `imaginary = abs_ * sin(angle)`

## Usage

```
op_polar(abs_, angle)
```

## Arguments

| | |
|---|---|
| `abs_` | The magnitude (absolute value) of the complex number. |
| `angle` | The angle (in radians) of the complex number. |

## Value

A complex number (or array of complex numbers) with the same shape as abs_ and angle.

## Examples

```
abs_ <- random_normal(c(1, 2))
angle <- random_normal(c(1, 2))
op_shape(op_polar(abs_, angle))

## shape(1, 2)

op_polar(abs_, angle)

## tf.Tensor([[-0.10252866-1.2460487j -0.2586355 -1.0352845j]], shape=(1, 2), dtype=complex64)
```

---

op_power *First tensor elements raised to powers from second tensor, element-wise.*

---

## Description

Note that this function is automatically called when using the R operator ^ with a tensor.

```
(x <- op_arange(4))

## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)

op_power(2, x)

## tf.Tensor([ 2.  4.  8. 16.], shape=(4), dtype=float32)

2 ^ x

## tf.Tensor([ 2.  4.  8. 16.], shape=(4), dtype=float32)
```

## Usage

```
op_power(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | The bases. |
| x2 | The exponents. |

## Value

Output tensor, the bases in x1 raised to the exponents in x2.

---

`op_prod` *Return the product of tensor elements over a given axis.*

---

## Description

Return the product of tensor elements over a given axis.

## Usage

```
op_prod(x, axis = NULL, keepdims = FALSE, dtype = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Axis or axes along which a product is performed. The default, `axis = NULL`, will compute the product of all elements in the input tensor. |
| `keepdims` | If this is set to `TRUE`, the axes which are reduce are left in the result as dimensions with size one. |
| `dtype` | Data type of the returned tensor. |

## Value

Product of elements of `x` over the given axis or axes.

`op_psnr` *Peak Signal-to-Noise Ratio (PSNR) function.*

---

## Description

This function computes the Peak Signal-to-Noise Ratio between two signals, `x1` and `x2`. PSNR is a measure of the quality of a reconstructed signal. The higher the PSNR, the closer the reconstructed signal is to the original signal. Note that it can become negative when the signal power is smaller that the noise power.

## Usage

```
op_psnr(x1, x2, max_val)
```

## Arguments

| | |
|---|---|
| `x1` | The first input signal. |
| `x2` | The second input signal. Must have the same shape as `x1`. |
| `max_val` | The maximum possible value in the signals. |

## Value

float: The PSNR value between `x1` and `x2`.

## Examples

```
x1 <- random_normal(c(2, 4, 4, 3))
x2 <- random_normal(c(2, 4, 4, 3))
max_val <- 1.0
op_psnr(x1, x2, max_val)

## tf.Tensor(-3.5293808, shape=(), dtype=float32)
```

---

op_qr *Computes the QR decomposition of a tensor.*

---

## Description

Computes the QR decomposition of a tensor.

## Usage

```
op_qr(x, mode = "reduced")
```

## Arguments

| | |
|---|---|
| x | Input tensor of shape `(..., M, N)`. |
| mode | A string specifying the mode of the QR decomposition.<br>• 'reduced': Returns the reduced QR decomposition. (default)<br>• 'complete': Returns the complete QR decomposition. |

## Value

A list containing two tensors. The first tensor of shape `(..., M, K)` is the orthogonal matrix q and the second tensor of shape (..., K, N)`is the upper triangular matrixr, where` K = min(M, N)‘.

## Examples

```
x <- op_convert_to_tensor(rbind(c(1, 2), c(3, 4), c(5, 6)))
op_qr(x)

## $q
## tf.Tensor(
## [[-0.16903085  0.89708523]
##  [-0.50709255  0.27602622]
##  [-0.84515425 -0.34503278]], shape=(3, 2), dtype=float64)
##
## $r
## tf.Tensor(
## [[-5.91607978 -7.43735744]
##  [ 0.          0.82807867]], shape=(2, 2), dtype=float64)

c(q, r) %<-% op_qr(x)
```

---

`op_quantile` *Compute the q-th quantile(s) of the data along the specified axis.*

---

## Description

Compute the q-th quantile(s) of the data along the specified axis.

## Usage

```
op_quantile(x, q, axis = NULL, method = "linear", keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `q` | Probability or sequence of probabilities for the quantiles to compute. Values must be between 0 and 1 inclusive. |
| `axis` | Axis or axes along which the quantiles are computed. Defaults to `axis=NULL` which is to compute the quantile(s) along a flattened version of the array. |
| `method` | A string specifies the method to use for estimating the quantile. Available methods are `"linear"`, `"lower"`, `"higher"`, `"midpoint"`, and `"nearest"`. Defaults to `"linear"`. If the desired quantile lies between two data points `i < j`:<br>• `"linear"`: `i + (j - i) * fraction`, where fraction is the fractional part of the index surrounded by `i` and `j`.<br>• `"lower"`: `i`.<br>• `"higher"`: `j`.<br>• `"midpoint"`: `(i + j) / 2`<br>• `"nearest"`: `i` or `j`, whichever is nearest. |
| `keepdims` | If this is set to `TRUE`, the axes which are reduce are left in the result as dimensions with size one. |

## Value

The quantile(s). If `q` is a single probability and `axis = NULL`, then the result is a scalar. If multiple probabilities levels are given, first axis of the result corresponds to the quantiles. The other axes are the axes that remain after the reduction of `x`.

`op_ravel` *Return a contiguous flattened tensor.*

---

## Description

A 1-D tensor, containing the elements of the input, is returned.

## Usage

```
op_ravel(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor.

op_real *Return the real part of the complex argument.*

---

## Description

Return the real part of the complex argument.

## Usage

```
op_real(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

The real component of the complex argument.

---

op_rearrange *Rearranges the axes of a Keras tensor according to a specified pattern,*

---

## Description

einops-style.

## Usage

```
op_rearrange(tensor, pattern, ...)
```

## Arguments

| | |
|---|---|
| tensor | Input Keras tensor. |
| pattern | String describing the rearrangement in einops notation. |
| ... | axes_lengths, named arguments specifying lengths of axes when axes decomposition is used. |

## Value

Tensor: A Keras tensor with rearranged axes.

Follows the logic of:

1. If decomposition is needed, reshape to match decomposed dimensions.
2. Permute known and inferred axes to match the form of the output.
3. Reshape to match the desired output shape.

Example Usage:

```
images <- op_ones(c(32, 30, 40, 3)) # BHWC format

# Reordering to BCHW
op_rearrange(images, 'b h w c -> b c h w') |> op_shape()

## shape(32, 3, 30, 40)

# "Merge" along first axis - concat images from a batch
op_rearrange(images, 'b h w c -> (b h) w c') |> op_shape()

## shape(960, 40, 3)

# "Merge" along second axis - concat images horizontally
op_rearrange(images, 'b h w c -> h (b w) c') |> op_shape()

## shape(30, 1280, 3)

# Flatten images into a CHW vector
op_rearrange(images, 'b h w c -> b (c h w)') |> op_shape()

## shape(32, 3600)

# Decompose H and W axes into 4 smaller patches
op_rearrange(images, 'b (h1 h) (w1 w) c -> (b h1 w1) h w c', h1 = 2, w1 = 2) |> op_shape()

## shape(128, 15, 20, 3)

# Space-to-depth decomposition of input axes
op_rearrange(images, 'b (h h1) (w w1) c -> b h w (c h1 w1)', h1 = 2, w1 = 2) |> op_shape()

## shape(32, 15, 20, 12)
```

---

`op_reciprocal` *Return the reciprocal of the argument, element-wise.*

---

## Description

Calculates `1/x`.

## Usage

```
op_reciprocal(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

Output tensor, element-wise reciprocal of `x`.

op_relu *Rectified linear unit activation function.*

---

## Description

It is defined as `f(x) = max(0, x)`.

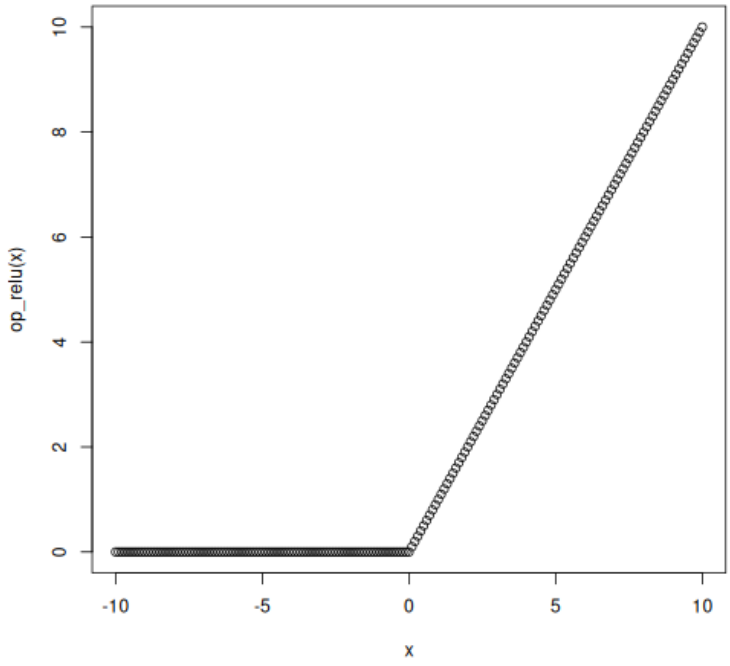
## Usage

```
op_relu(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value



A tensor with the same shape as `x`.

## Examples

```
x1 <- op_convert_to_tensor(c(-1, 0, 1, 0.2))
op_relu(x1)
```

```
## tf.Tensor([0.  0.  1.  0.2], shape=(4), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_relu(x))
```

`op_relu6` *Rectified linear unit activation function with upper bound of 6.*

---

## Description

It is defined as `f(x) = op_clip(x, 0, 6)`.

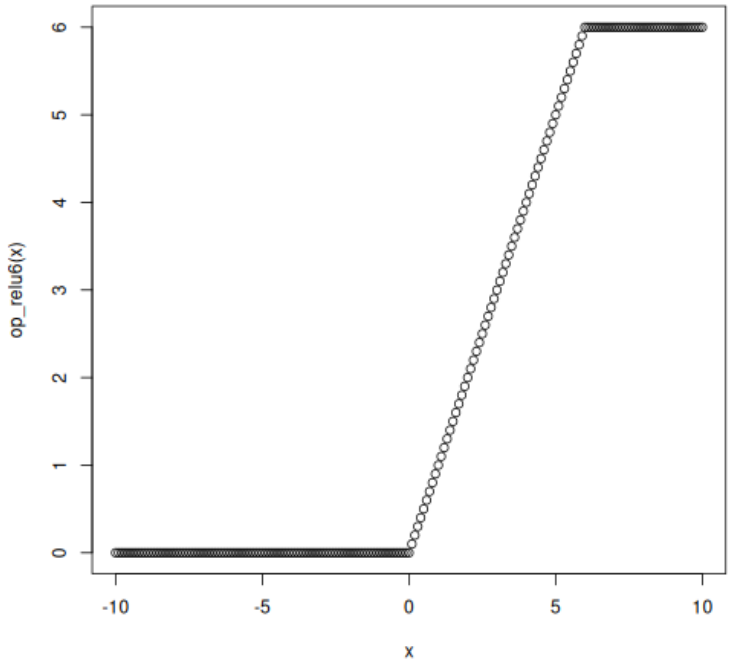
## Usage

```
op_relu6(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value



A tensor with the same shape as `x`.

## Examples

```
x <- op_convert_to_tensor(c(-3, -2, 0.1, 0.2, 6, 8))
op_relu6(x)

## tf.Tensor([0.  0.  0.1 0.2 6.  6. ], shape=(6), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_relu6(x))
```

`op_repeat` *Repeat each element of a tensor after themselves.*

---

## Description

Repeat each element of a tensor after themselves.

## Usage

```
op_repeat(x, repeats, axis = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `repeats` | The number of repetitions for each element. |
| `axis` | The axis along which to repeat values. By default, use the flattened input array, and return a flat output array. |

## Value

Output tensor.

`op_reshape` *Gives a new shape to a tensor without changing its data.*

---

## Description

Gives a new shape to a tensor without changing its data.

## Usage

```
op_reshape(x, newshape)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `newshape` | The new shape should be compatible with the original shape. One shape dimension can be `-1` in which case the value is inferred from the length of the array and remaining dimensions. |

## Value

The reshaped tensor.

---

`op_rfft` *Real-valued Fast Fourier Transform along the last axis of the input.*

---

## Description

Computes the 1D Discrete Fourier Transform of a real-valued signal over the inner-most dimension of input.

Since the Discrete Fourier Transform of a real-valued signal is Hermitian-symmetric, RFFT only returns the `fft_length / 2 + 1` unique components of the FFT: the zero-frequency term, followed by the `fft_length / 2` positive-frequency terms.

Along the axis RFFT is computed on, if `fft_length` is smaller than the corresponding dimension of the input, the dimension is cropped. If it is larger, the dimension is padded with zeros.

## Usage

```
op_rfft(x, fft_length = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `fft_length` | An integer representing the number of the fft length. If not specified, it is inferred from the length of the last axis of `x`. Defaults to `NULL`. |

## Value

A list containing two tensors - the real and imaginary parts of the output.

## Examples

```
x <- op_convert_to_tensor(c(0, 1, 2, 3, 4))
op_rfft(x)

## [[1]]
## tf.Tensor([10.  -2.5 -2.5], shape=(3), dtype=float64)
##
## [[2]]
## tf.Tensor([0.         3.4409548  0.81229924], shape=(3), dtype=float64)

op_rfft(x, 3)

## [[1]]
## tf.Tensor([ 3.  -1.5], shape=(2), dtype=float64)
##
## [[2]]
## tf.Tensor([0.        0.8660254], shape=(2), dtype=float64)
```

---

`op_right_shift` *Shift the bits of an integer to the right.*

---

## Description

Bits are shifted to the right `y`. Because the internal representation of numbers is in binary format, this operation is equivalent to dividing `x` by `2^y`.

## Usage

```
op_right_shift(x, y)
```

## Arguments

| | |
|---|---|
| x | Input integer tensor. |
| y | Input integer tensor. |

## Value

Result tensor.

---

`op_rms_normalization` *Performs Root Mean Square (RMS) normalization on* `x`.

---

## Description

The Keras operation implements the operation as described in Root Mean Square Layer Normalization by Biao Zhang et al.

The operation is different from LayerNormalization with RMS scaling.

It is defined as `rms_normalization(x) = x * rsqrt(mean(square(x))) * scale`

## Usage

```
op_rms_normalization(x, scale = NULL, axis = -1L, epsilon = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| scale | Optional scaling factor for the normalization. |
| axis | The axis or axes along which to perform normalization. Defaults to -1. |
| epsilon | A lower bound value for the norm. Defaults to config_epsilon(). |

## Value

The normalized array.

## Examples

```
x <- random_normal(c(1, 10))
op_rms_normalization(x)
op_rms_normalization(x, scale = 10)
```

op_roll *Roll tensor elements along a given axis.*

---

## Description

Elements that roll beyond the last position are re-introduced at the first.

## Usage

```
op_roll(x, shift, axis = NULL)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| shift | The number of places by which elements are shifted. |
| axis | The axis along which elements are shifted. By default, the array is flattened before shifting, after which the original shape is restored. |

## Value

Output tensor.

op_rot90 *Rotate an array by 90 degrees in the plane specified by axes.*

---

## Description

This function rotates an array counterclockwise by 90 degrees k times in the plane specified by axes. Supports arrays of two or more dimensions.

## Usage

```
op_rot90(array, k = 1L, axes = list(1L, 2L))
```

## Arguments

| | |
|---|---|
| array | Input array to rotate. |
| k | Number of times the array is rotated by 90 degrees. |
| axes | A tuple of two integers specifying the plane of rotation (defaults to (1, 2)). |

## Value

Rotated array.

## Examples

```
m <- 1:4 |> op_reshape(c(2, 2))
m

## tf.Tensor(
## [[1 2]
##  [3 4]], shape=(2, 2), dtype=int32)
```

```
op_rot90(m)

## tf.Tensor(
## [[2 4]
##  [1 3]], shape=(2, 2), dtype=int32)

m <- 1:8 |> op_reshape(c(2, 2, 2))
m

## tf.Tensor(
## [[[1 2]
##   [3 4]]
##
##  [[5 6]
##   [7 8]]], shape=(2, 2, 2), dtype=int32)

op_rot90(m, k = 1, axes = c(2, 3))

## tf.Tensor(
## [[[2 4]
##   [1 3]]
##
##  [[6 8]
##   [5 7]]], shape=(2, 2, 2), dtype=int32)
```

op_round *Evenly round to the given number of decimals.*

---

## Description

Evenly round to the given number of decimals.

## Usage

```
op_round(x, decimals = 0L)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| decimals | Number of decimal places to round to. Defaults to 0. |

## Value

Output tensor.

op_rsqrt *Computes reciprocal of square root of x element-wise.*

## Description

Computes reciprocal of square root of x element-wise.

## Usage

```
op_rsqrt(x)
```

## Arguments

| | |
|---|---|
| x | input tensor |

## Value

A tensor with the same dtype as x.

## Examples

```
x <- op_convert_to_tensor(c(1, 10, 100))
op_rsqrt(x)
```

```
## tf.Tensor([1.         0.31622777 0.1       ], shape=(3), dtype=float64)
```

```
# array([1, 0.31622776, 0.1], dtype=float32)
```

---

`op_saturate_cast` *Performs a safe saturating cast to the desired dtype.*

---

## Description

Saturating cast prevents data type overflow when casting to `dtype` with smaller values range. E.g. `op_cast(c(-1, 256), "float32") |> op_cast("uint8")` returns `c(255, 0)`, but `op_cast(c(-1, 256), "float32") |> op_saturate_cast("uint8")` returns `c(0, 255)`.

## Usage

```
op_saturate_cast(x, dtype)
```

## Arguments

| | |
|---|---|
| `x` | A tensor or variable. |
| `dtype` | The target type. |

## Value

A safely casted tensor of the specified `dtype`.

## Examples

Image resizing with bicubic interpolation may produce values outside original range.

```
image2x2 <- np_array(as.integer(c(0, 1, 254, 255)), "uint8") |>
  array_reshape(c(1, 2, 2, 1))
image4x4 <- image2x2 |>
  tensorflow::tf$image$resize(shape(4, 4), method="bicubic")
image4x4 |> as.array() |> drop()
```

```
##           [,1]      [,2]      [,3]      [,4]
## [1,] -22.50000 -22.20462 -21.61891 -21.32353
## [2,]  52.52605  52.82143  53.40715  53.70253
## [3,] 201.29752 201.59288 202.17859 202.47395
## [4,] 276.32355 276.61893 277.20465 277.50006
```

Casting this resized image back to `uint8` will cause overflow.

```
image4x4_casted <- op_cast(image4x4, "uint8")
image4x4_casted |> as.array() |> drop()
```

```
##      [,1] [,2] [,3] [,4]
## [1,]  234  234  235  235
## [2,]   52   52   53   53
## [3,]  201  201  202  202
## [4,]   20   20   21   21
```

Saturate casting to `uint8` will clip values to `uint8` range before casting and will not cause overflow.

```
image4x4_saturate_casted <- image4x4 |> op_saturate_cast("uint8")
image4x4_saturate_casted |> as.array() |> drop()
```

```
##      [,1] [,2] [,3] [,4]
## [1,]    0    0    0    0
## [2,]   52   52   53   53
## [3,]  201  201  202  202
## [4,]  255  255  255  255
```

---

op_scan *Scan a function over leading array axes while carrying along state.*

---

## Description

When the type of xs is an array type or NULL, and the type of ys is an array type, the semantics of op_scan() are given roughly by this implementation:

```
op_scan <- function(f, init, xs = NULL, length = NULL) {
  xs <- xs %||% vector("list", length)
  if(!is.list(xs))
    xs <- op_unstack(xs)
  ys <- vector("list", length(xs))
  carry <- init
  for (i in seq_along(xs)) {
```

```
    c(carry, y) %<-% f(carry, xs[[i]])
    ys[[i]] <- y
  }
  list(carry, op_stack(ys))
}
```

The loop-carried value `carry` (`init`) must hold a fixed shape and dtype across all iterations.

In TensorFlow, `y` must match `carry` in shape and dtype. This is not required in other backends.

## Usage

```
op_scan(f, init, xs = NULL, length = NULL, reverse = FALSE, unroll = 1L)
```

## Arguments

| | |
|---|---|
| `f` | Callable defines the logic for each loop iteration. This accepts two arguments where the first is a value of the loop carry and the second is a slice of `xs` along its leading axis. This callable returns a pair where the first represents a new value for the loop carry and the second represents a slice of the output. |
| `init` | The initial loop carry value. This can be a scalar, tensor, or any nested structure. It must match the structure of the first element returned by `f`. |
| `xs` | Optional value to scan along its leading axis. This can be a tensor or any nested structure. If `xs` is not provided, you must specify `length` to define the number of loop iterations. Defaults to `NULL`. |
| `length` | Optional integer specifying the number of loop iterations. If `length` is not provided, it defaults to the sizes of leading axis of the arrays in `xs`. Defaults to `NULL`. |
| `reverse` | Optional boolean specifying whether to run the scan iteration forward or in reverse, equivalent to reversing the leading axes of the arrays in both `xs` and in `ys`. |
| `unroll` | Optional positive integer or boolean specifying how many scan iterations to unroll within a single iteration of a loop. If an integer is provided, it determines how many unrolled loop iterations to run within a single rolled iteration of the loop. If a boolean is provided, it will determine if the loop is completely unrolled (`unroll=TRUE`) or left completely unrolled (`unroll=FALSE`). Note that unrolling is only supported by JAX and TensorFlow backends. |

## Value

A pair where the first element represents the final loop carry value and the second element represents the stacked outputs of `f` when scanned over the leading axis of the inputs.

## Examples

```
sum_fn <- function(c, x) list(c + x, c + x)
init <- op_array(0L)
xs <- op_array(1:5)
```

```
c(carry, result) %<-% op_scan(sum_fn, init, xs)
carry
```

```
## tf.Tensor(15, shape=(), dtype=int32)
```

```
result
```

```
## tf.Tensor([ 1  3  6 10 15], shape=(5), dtype=int32)
```

---

`op_scatter` *Returns a tensor of shape* `shape` *where* `indices` *are set to* `values`.

---

## Description

At a high level, this operation does `zeros[indices] = updates` and returns the output. It is equivalent to:

```
output <- op_scatter_update(op_zeros(shape), indices, values)
```

## Usage

```
op_scatter(indices, values, shape)
```

## Arguments

| | |
|---|---|
| indices | A tensor or list specifying indices for the values in values. |
| values | A tensor, the values to be set at indices. |
| shape | Shape of the output tensor. |

## Value

A tensor of shape shape where indices are set to values.

## Examples

```
op_scatter(indices = rbind(1), values = 1, shape = c(5))

## tf.Tensor([1. 0. 0. 0. 0.], shape=(5), dtype=float64)

op_scatter(indices = rbind(1, 3), values = 1:2, shape = c(5))

## tf.Tensor([1 0 2 0 0], shape=(5), dtype=int32)

indices <- rbind(c(1, 2), c(2, 2))
values <- op_array(c(1, 1))
op_scatter(indices, values, shape = c(2, 2))

## tf.Tensor(
## [[0. 1.]
##  [0. 1.]], shape=(2, 2), dtype=float32)
```

`op_scatter_update` *Update inputs via updates at scattered (sparse) indices.*

---

## Description

At a high level, this operation does `inputs[indices] <- updates`. Assume `inputs` is a tensor of shape `(D1, D2, ..., Dn)`, there are 2 main usages of `scatter_update`.

1. `indices` is a 2D tensor of shape `(num_updates, n)`, where `num_updates` is the number of updates to perform, and `updates` is a 1D tensor of shape `(num_updates)`. For example, if `inputs` is `op_zeros(c(4, 4, 4))`, and we want to update `inputs[2, 3, 4]` and `inputs[1, 2, 4]` as 1, then we can use:

```
inputs <- op_zeros(c(4, 4, 4))
indices <- rbind(c(2, 3, 4),
                 c(1, 2, 4))
updates <- op_array(c(1, 1), "float32")
op_scatter_update(inputs, indices, updates)
```

```
## tf.Tensor(
## [[[0. 0. 0. 0.]
##   [0. 0. 0. 1.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 1.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]], shape=(4, 4, 4), dtype=float32)
```

2 indices is a 2D tensor of shape (num_updates, k), where num_updates is the number of updates to perform, and k (k <= n) is the size of each index in indices. updates is a n - k-D tensor of shape (num_updates, shape(inputs)[-(1:k)]). For example, if inputs <- op_zeros(c(4, 4, 4)), and we want to update inputs[1, 2, ] and inputs[2, 3, ] as [1, 1, 1, 1], then indices would have shape (num_updates, 2) (k = 2), and updates would have shape (num_updates, 4) (shape(inputs)[3:4] == 4). See the code below:

```
inputs <- op_zeros(c(4, 4, 4))
indices <- rbind(c(2, 3),
                 c(3, 4))
updates <- op_array(rbind(c(1, 1, 1, 1),
                          c(1, 1, 1, 1)),
                    "float32")
op_scatter_update(inputs, indices, updates)
```

```
## tf.Tensor(
## [[[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [1. 1. 1. 1.]
##   [0. 0. 0. 0.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [1. 1. 1. 1.]]
##
##  [[0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]
##   [0. 0. 0. 0.]]], shape=(4, 4, 4), dtype=float32)
```

## Usage

```
op_scatter_update(inputs, indices, updates)
```

## Arguments

| | |
|---|---|
| inputs | A tensor, the tensor to be updated. |
| indices | A tensor or list of shape (N, inputs$ndim), specifying indices to update. N is the number of indices to update, must be equal to the first dimension of updates. |
| updates | A tensor, the new values to be put to inputs at indices. |

## Value

A tensor, has the same shape and dtype as `inputs`.

`op_searchsorted` *Perform a binary search.*

---

## Description

Return insertion indices that keep `values` in sorted order when placed into `sorted_sequence`.

## Usage

```
op_searchsorted(sorted_sequence, values, side = "left", zero_indexed = FALSE)
```

## Arguments

| | |
|---|---|
| `sorted_sequence` | 1-D input tensor that is sorted along its innermost dimension. |
| `values` | N-D tensor of query insertion values. |
| `side` | Either `"left"` or `"right"`, choosing which side to insert on ties. |
| `zero_indexed` | If `TRUE`, the returned indices are zero-based (`0` encodes the first position); if `FALSE` (default), the returned indices are one-based (`1` encodes the first position). |

## Value

Tensor of insertion indices with the same shape as `values`.

## Examples

```
sorted <- op_array(c(-1, 0, 2, 4))
queries <- c(-2, 0, 3, 7)
op_searchsorted(sorted, queries)

## tf.Tensor([1 2 4 5], shape=(4), dtype=int32)

op_searchsorted(sorted, queries, side = "right", zero_indexed = TRUE)

## tf.Tensor([0 2 3 4], shape=(4), dtype=int32)
```

op_segment_max *Computes the max of segments in a tensor.*

---

## Description

Computes the max of segments in a tensor.

## Usage

```
op_segment_max(data, segment_ids, num_segments = NULL, sorted = FALSE)
```

## Arguments

| | |
|---|---|
| data | Input tensor. |
| segment_ids | A N-D tensor containing segment indices for each element in data. head(op_shape(data), length(op_shape(segment_ids))) should match op_shape(segment_ids) |
| num_segments | An integer representing the total number of segments. If not specified, it is inferred from the maximum value in segment_ids. |
| sorted | A boolean indicating whether segment_ids is sorted. Defaults to FALSE. |

## Value

A tensor containing the max of segments, where each element represents the max of the corresponding segment in data.

## Examples

```
data <- op_convert_to_tensor(c(1, 2, 10, 20, 100, 200))
segment_ids <- op_array(c(1, 1, 2, 2, 3, 3), "int32")
num_segments <- 3
op_segment_max(data, segment_ids, num_segments)

## tf.Tensor([  2.  20. 200.], shape=(3), dtype=float64)

# array([2, 20, 200], dtype=int32)
```

`op_segment_sum` *Computes the sum of segments in a tensor.*

---

## Description

Computes the sum of segments in a tensor.

## Usage

```
op_segment_sum(data, segment_ids, num_segments = NULL, sorted = FALSE)
```

## Arguments

| | |
|---|---|
| data | Input tensor. |
| segment_ids | A N-D tensor containing segment indices for each element in data. Num dims for segment ids should be strictly smaller or equal to number of dims in data. |
| num_segments | An integer representing the total number of segments. If not specified, it is inferred from the maximum value in segment_ids. |
| sorted | A boolean indicating whether segment_ids is sorted. Defaults to FALSE. |

## Value

A tensor containing the sum of segments, where each element represents the sum of the corresponding segment in data.

## Examples

```
data <- op_array(c(1, 2, 10, 20, 100, 200))
segment_ids <- op_array(c(1, 1, 2, 2, 3, 3), "int32")
num_segments <- 3
op_segment_sum(data, segment_ids, num_segments)

## tf.Tensor([  3.  30. 300.], shape=(3), dtype=float32)
```

op_select *Return elements from* choicelist*, based on conditions in* condlist.

---

## Description

Return elements from `choicelist`, based on conditions in `condlist`.

## Usage

```
op_select(condlist, choicelist, default = 0L)
```

## Arguments

| | |
|---|---|
| `condlist` | List of boolean tensors. The list of conditions which determine from which array in choicelist the output elements are taken. When multiple conditions are satisfied, the first one encountered in condlist is used. |
| `choicelist` | List of tensors. The list of tensors from which the output elements are taken. This list has to be of the same length as `condlist`. |
| `default` | Optional scalar value. The element inserted in the output when all conditions evaluate to `FALSE`. |

## Value

Tensor where the output at position `m` is the `m`-th element of the tensor in `choicelist` where the `m`-th element of the corresponding tensor in `condlist` is `TRUE`.

## Examples

```
x <- op_arange(6L)
condlist <- list(x < 3, x > 3)
choicelist <- list(x, x^2)
op_select(condlist, choicelist, 42)

## tf.Tensor([ 1  2 42 16 25 36], shape=(6), dtype=int32)
```

op_selu *Scaled Exponential Linear Unit (SELU) activation function.*

---

## Description

It is defined as:
`f(x) = scale * alpha * (exp(x) - 1.) for x < 0`, `f(x) = scale * x for x >= 0`.

## Usage

```
op_selu(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1, 0, 1))
op_selu(x)
```

```
## tf.Tensor([-1.1113307  0.         1.050701 ], shape=(3), dtype=float32)
```

`op_separable_conv` *General N-D separable convolution.*

---

## Description

This ops supports 1D and 2D separable convolution. `separable_conv` is a depthwise conv followed by a pointwise conv.

## Usage

```
op_separable_conv(
  inputs,
  depthwise_kernel,
  pointwise_kernel,
```

```
  strides = 1L,
  padding = "valid",
  data_format = NULL,
  dilation_rate = 1L
)
```

## Arguments

| | |
|---|---|
| inputs | Tensor of rank N+2. inputs has shape (batch_size,) + inputs_spatial_shape + (num_channels,) if data_format="channels_last", or (batch_size, num_channels) + inputs_spatial_shape if data_format="channels_first". |
| depthwise_kernel | Tensor of rank N+2. depthwise_kernel has shape [kernel_spatial_shape, num_input_channels, r num_input_channels should match the number of channels in inputs. |
| pointwise_kernel | Tensor of rank N+2. pointwise_kernel has shape (*ones_like(kernel_spatial_shape), num_inpu |
| strides | int or int tuple/list of len(inputs_spatial_shape), specifying the strides of the convolution along each spatial dimension. If strides is int, then every spatial dimension shares the same strides. |
| padding | string, either "valid" or "same". "valid" means no padding is applied, and "same" results in padding evenly to the left/right or up/down of the input such that output has the same height/width dimension as the input when strides=1. |
| data_format | A string, either "channels_last" or "channels_first". data_format determines the ordering of the dimensions in the inputs. If data_format="channels_last", inputs is of shape (batch_size, ..., channels) while if data_format="channels_first", inputs is of shape (batch_size, channels, ...). |
| dilation_rate | int or int tuple/list of len(inputs_spatial_shape), specifying the dilation rate to use for dilated convolution. If dilation_rate is int, then every spatial dimension shares the same dilation_rate. |

## Value

A tensor of rank N+2, the result of the depthwise conv operation.

---

op_shape *Gets the shape of the tensor input.*

---

## Description

Gets the shape of the tensor input.

## Usage

```
op_shape(x)
```

## Arguments

| | |
|---|---|
| x | A tensor. This function will try to access the shape attribute of the input tensor. |

## Value

A list of integers or NULL values, indicating the shape of the input tensor.

## Note

On the TensorFlow backend, when `x` is a `tf.Tensor` with dynamic shape, dimensions which are dynamic in the context of a compiled function will have a `tf.Tensor` value instead of a static integer value.

## Examples

```
x <- op_zeros(c(8, 12))
op_shape(x)

## shape(8, 12)
```

`op_sigmoid` *Sigmoid activation function.*

---

## Description

It is defined as `f(x) = 1 / (1 + exp(-x))`.

## Usage

```
op_sigmoid(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A tensor with the same shape as x.

## Examples

```
x <- op_convert_to_tensor(c(-6, 1, 0, 1, 6))
op_sigmoid(x)
```

```
## tf.Tensor([0.00247262 0.73105858 0.5      0.73105858 0.99752738], shape=(5), dtype=float64)
```

---

op_signbit *Return the sign bit of the elements of* x.

---

## Description

The output boolean tensor contains TRUE where the sign of x is negative, and FALSE otherwise.

## Usage

```
op_signbit(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output boolean tensor of same shape as x.

op_silu *Sigmoid Linear Unit (SiLU) activation function, also known as Swish.*

---

## Description

The SiLU activation function is computed by the sigmoid function multiplied by its input. It is defined as `f(x) = x * sigmoid(x)`.

## Usage

```
op_silu(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_convert_to_tensor(c(-6, 1, 0, 1, 6))
op_sigmoid(x)
```

```
## tf.Tensor([0.00247262 0.73105858 0.5      0.73105858 0.99752738], shape=(5), dtype=float64)
```

```
op_silu(x)
```

```
## tf.Tensor([-0.01483574  0.73105858  0.       0.73105858  5.98516426], shape=(5), dtype=float64)
```

`op_sin` *Trigonometric sine, element-wise.*

---

## Description

Trigonometric sine, element-wise.

## Usage

```
op_sin(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor of same shape as x.

`op_size` *Return the number of elements in a tensor.*

---

## Description

Return the number of elements in a tensor.

## Usage

```
op_size(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Number of elements in `x`.

---

op_slice *Return a slice of an input tensor.*

---

## Description

At a high level, this operation is an explicit replacement for array slicing e.g. `inputs[start_indices:(start_indices + shape)]`. Unlike slicing via brackets, this operation will accept tensor start indices on all backends, which is useful when indices dynamically computed via other tensor operations.

```
(inputs <- op_arange(5*5) |> op_reshape(c(5, 5)))
```

```
## tf.Tensor(
## [[ 1.  2.  3.  4.  5.]
##  [ 6.  7.  8.  9. 10.]
##  [11. 12. 13. 14. 15.]
##  [16. 17. 18. 19. 20.]
##  [21. 22. 23. 24. 25.]], shape=(5, 5), dtype=float32)
```

```
start_indices <- c(3, 3)
shape <- c(2, 2)
op_slice(inputs, start_indices, shape)
```

```
## tf.Tensor(
## [[13. 14.]
##  [18. 19.]], shape=(2, 2), dtype=float32)
```

## Usage

```
op_slice(inputs, start_indices, shape)
```

## Arguments

| | |
|---|---|
| inputs | A tensor, the tensor to be sliced. |
| start_indices | A list of length inputs$ndim, specifying the starting indices for updating. |
| shape | The full shape of the returned slice. |

## Value

A tensor, has the same shape and dtype as inputs.

---

`op_slice_update` *Update an input by slicing in a tensor of updated values.*

---

## Description

At a high level, this operation does `inputs[start_indices: start_indices + updates.shape] = updates`. Assume inputs is a tensor of shape `(D1, D2, ..., Dn)`, `start_indices` must be a list of n integers, specifying the starting indices. `updates` must have the same rank as `inputs`, and the size of each dim must not exceed `Di - start_indices[i]`. For example, if we have 2D inputs `inputs = op_zeros(c(5, 5))`, and we want to update the intersection of last 2 rows and last 2 columns as 1, i.e., `inputs[4:5, 4:5] = op_ones(c(2, 2))`, then we can use the code below:

```
inputs <- op_zeros(c(5, 5))
start_indices <- c(3, 3)
updates <- op_ones(c(2, 2))
op_slice_update(inputs, start_indices, updates)

## tf.Tensor(
## [[0. 0. 0. 0. 0.]
##  [0. 0. 0. 0. 0.]
##  [0. 0. 1. 1. 0.]
##  [0. 0. 1. 1. 0.]
##  [0. 0. 0. 0. 0.]], shape=(5, 5), dtype=float32)
```

## Usage

```
op_slice_update(inputs, start_indices, updates)
```

## Arguments

| | |
|---|---|
| `inputs` | A tensor, the tensor to be updated. |
| `start_indices` | A list of length `inputs$ndim`, specifying the starting indices for updating. |
| `updates` | A tensor, the new values to be put to `inputs` at `indices`. `updates` must have the same rank as `inputs`. |

## Value

A tensor, has the same shape and dtype as `inputs`.

`op_slogdet` *Compute the sign and natural logarithm of the determinant of a matrix.*

---

## Description

Compute the sign and natural logarithm of the determinant of a matrix.

## Usage

```
op_slogdet(x)
```

## Arguments

| | |
|---|---|
| x | Input matrix. It must 2D and square. |

## Value

A list: `(sign, logabsdet)`. `sign` is a number representing the sign of the determinant. For a real matrix, this is 1, 0, or -1. For a complex matrix, this is a complex number with absolute value 1 (i.e., it is on the unit circle), or else 0. `logabsdet` is the natural log of the absolute value of the determinant.

---

`op_softmax` *Softmax activation function.*

---

## Description

The elements of the output vector lie within the range `(0, 1)`, and their total sum is exactly 1 (excluding the floating point rounding error).

Each vector is processed independently. The `axis` argument specifies the axis along which the function is applied within the input.

It is defined as: `f(x) = exp(x) / sum(exp(x))`

## Usage

```
op_softmax(x, axis = -1L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Integer, axis along which the softmax is applied. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1, 0, 1))
op_softmax(x)

## tf.Tensor([0.09003057 0.24472848 0.66524094], shape=(3), dtype=float32)
```

`op_softplus` *Softplus activation function.*

---

## Description

It is defined as `f(x) = log(exp(x) + 1)`, where `log` is the natural logarithm and `exp` is the exponential function.

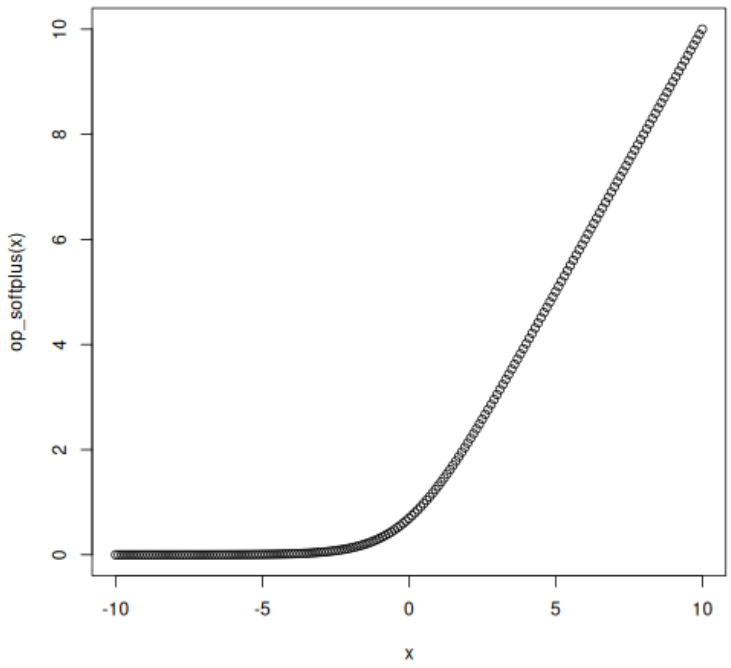
## Usage

```
op_softplus(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value



A tensor with the same shape as `x`.

## Examples

```
x <- op_convert_to_tensor(c(-0.555, 0, 0.555))
op_softplus(x)

## tf.Tensor([0.45366606 0.69314718 1.00866606], shape=(3), dtype=float64)

x <- seq(-10, 10, .1)
plot(x, op_softplus(x))
```

`op_softsign` *Softsign activation function.*

---

## Description

It is defined as `f(x) = x / (abs(x) + 1)`.

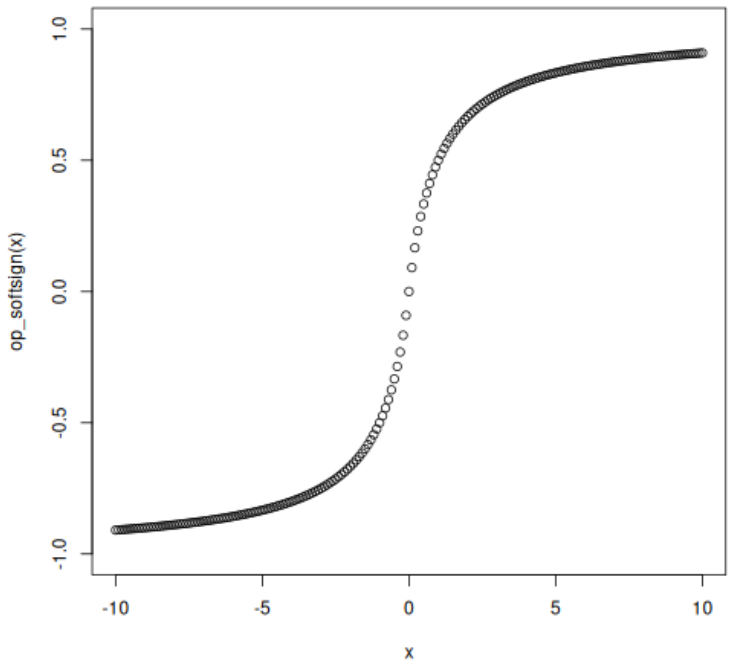
## Usage

```
op_softsign(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value



A tensor with the same shape as x.

## Examples

```
x <- op_convert_to_tensor(c(-0.100, -10.0, 1.0, 0.0, 100.0))
op_softsign(x)
```

```
## tf.Tensor([-0.09090909 -0.90909091  0.5       0.        0.99009901], shape=(5), dtype=float64)
```

```
x <- seq(-10, 10, .1)
plot(x, op_softsign(x), ylim = c(-1, 1))
```

`op_soft_shrink` *Soft Shrink activation function.*

---

## Description

It is defined as

`f(x) = x - threshold` if `x > threshold`, `f(x) = x + threshold` if `x < -threshold`, `f(x) = 0` otherwise.

## Usage

```
op_soft_shrink(x, threshold = 0.5)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| threshold | Threshold value. Defaults to 0.5. |

## Value

A tensor with the same shape as x.

## Examples

```
x <- op_array(c(-1, 0, 1))
op_soft_shrink(x)
```

```
## tf.Tensor([-0.5  0.   0.5], shape=(3), dtype=float32)
```

`op_solve` *Solves a linear system of equations given by* `a x = b`.

---

## Description

Solves for `x` in the equation `a %*% x == b`.

## Usage

```
op_solve(a, b)
```

## Arguments

| | |
|---|---|
| `a` | A tensor of shape `(..., M, M)` representing the coefficients matrix. |
| `b` | A tensor of shape `(..., M)` or `(..., M, N)` representing the right-hand side or "dependent variable" matrix. |

## Value

A tensor of shape `(..., M)` or `(..., M, N)` representing the solution of the linear system. Returned shape is identical to `b`.

## Examples

```
a <- op_array(c(1, 2, 4, 5), dtype="float32") |> op_reshape(c(2, 2))
b <- op_array(c(2, 4, 8, 10), dtype="float32") |> op_reshape(c(2, 2))
op_solve(a, b)

## tf.Tensor(
## [[2. 0.]
##  [0. 2.]], shape=(2, 2), dtype=float32)
```

`op_solve_triangular` *Solves a linear system of equations given by* `a %*% x = b`.

---

## Description

Solves a linear system of equations given by `a %*% x = b`.

## Usage

```
op_solve_triangular(a, b, lower = FALSE)
```

## Arguments

| | |
|---|---|
| `a` | A tensor of shape `(..., M, M)` representing the coefficients matrix. |
| `b` | A tensor of shape `(..., M)` or `(..., M, N)` representing the right-hand side or "dependent variable" matrix. |
| `lower` | logical. Use only data contained in the lower triangle of `a`. Default is to use upper triangle. |

## Value

A tensor of shape `(..., M)` or `(..., M, N)` representing the solution of the linear system. Returned shape is identical to `b`.

op_sort *Sorts the elements of* x *along a given axis in ascending order.*

## Description

Sorts the elements of x along a given axis in ascending order.

## Usage

```
op_sort(x, axis = -1L)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis along which to sort. If NULL, the tensor is flattened before sorting. Defaults to -1; the last axis. |

## Value

Sorted tensor.

`op_sparsemax` *Sparsemax activation function.*

---

## Description

For each batch `i`, and class `j`, sparsemax activation function is defined as:
`sparsemax(x)[i, j] = max(x[i, j] - (x[i, :]), 0)`.

## Usage

```
op_sparsemax(x, axis = -1L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | `int`, axis along which the sparsemax operation is applied. |

## Value

A tensor, output of sparsemax transformation. Has the same type and shape as `x`.

## Examples

```
x <- op_array(c(-1., 0., 1.))
op_sparsemax(x)

## tf.Tensor([0. 0. 1.], shape=(3), dtype=float32)
```

---

`op_sparse_categorical_crossentropy`
*Computes sparse categorical cross-entropy loss.*

---

## Description

The sparse categorical cross-entropy loss is similar to categorical cross-entropy, but it is used when the target tensor contains integer class labels instead of one-hot encoded vectors. It measures the dissimilarity between the target and output probabilities or logits.

## Usage

```
op_sparse_categorical_crossentropy(
  target,
  output,
  from_logits = FALSE,
  axis = -1L
)
```

## Arguments

| | |
|---|---|
| `target` | The target tensor representing the true class labels as integers. Its shape should match the shape of the `output` tensor except for the last dimension. |
| `output` | The output tensor representing the predicted probabilities or logits. Its shape should match the shape of the `target` tensor except for the last dimension. |

| | |
|---|---|
| from_logits | (optional) Whether output is a tensor of logits or probabilities. Set it to TRUE if output represents logits; otherwise, set it to FALSE if output represents probabilities. Defaults to FALSE. |
| axis | (optional) The axis along which the sparse categorical cross-entropy is computed. Defaults to -1, which corresponds to the last dimension of the tensors. |

## Value

Integer tensor: The computed sparse categorical cross-entropy loss between target and output.

## Examples

```
target <- op_array(c(0, 1, 2), dtype="int32")
output <- op_array(rbind(c(0.9, 0.05, 0.05),
                         c(0.1, 0.8,  0.1),
                         c(0.2, 0.3,  0.5)))
op_sparse_categorical_crossentropy(target, output)

## tf.Tensor([0.10536052 0.22314355 0.69314718], shape=(3), dtype=float64)
```

`op_sparse_plus` *SparsePlus activation function.*

---

## Description

It is defined as

`f(x) = 0` for `x <= -1`. `f(x) = (1/4) * (x + 1)^2` for `-1 < x < 1`. `f(x) = x` for `x >= 1`.

## Usage

```
op_sparse_plus(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1.0, 0.0, 1.0))
op_sparse_plus(x)
```

```
## tf.Tensor([0.   0.25 1.  ], shape=(3), dtype=float32)
```

`op_sparse_sigmoid` *Sparse sigmoid activation function.*

---

## Description

It is defined as

`f(x) = 0` for `x <= -1`, `f(x) = 0.5 * (x + 1)` for `-1 < x < 1`, `f(x) = 1` for `x >= 1`.

## Usage

```
op_sparse_sigmoid(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1.0, 0.0, 1.0))
op_sparse_sigmoid(x)

## tf.Tensor([0.  0.5 1. ], shape=(3), dtype=float32)
```

`op_split` *Split a tensor into chunks.*

---

## Description

Split a tensor into chunks.

## Usage

```
op_split(x, indices_or_sections, axis = 1L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `indices_or_sections` | If an integer, N, the tensor will be split into N equal sections along `axis`. If a 1-D array of sorted integers, the entries indicate indices at which the tensor will be split along `axis`. |
| `axis` | Axis along which to split. Defaults to `1`, the first axis. |

## Value

A list of tensors.

## Note

A split does not have to result in equal division when using Torch backend.

## Example

```
x <- op_arange(12)

# pass a scalar integer for n sections
op_split(x, 2)

## [[1]]
## tf.Tensor([1. 2. 3. 4. 5. 6.], shape=(6), dtype=float32)
##
## [[2]]
## tf.Tensor([ 7.  8.  9. 10. 11. 12.], shape=(6), dtype=float32)

op_split(x, 3)

## [[1]]
## tf.Tensor([1. 2. 3. 4.], shape=(4), dtype=float32)
##
## [[2]]
## tf.Tensor([5. 6. 7. 8.], shape=(4), dtype=float32)
##
## [[3]]
## tf.Tensor([ 9. 10. 11. 12.], shape=(4), dtype=float32)

# 1-d array/tensor for indices
op_split(x, array(c(3, 8)))

## [[1]]
## tf.Tensor([1. 2.], shape=(2), dtype=float32)
##
## [[2]]
## tf.Tensor([3. 4. 5. 6. 7.], shape=(5), dtype=float32)
##
## [[3]]
## tf.Tensor([ 8.  9. 10. 11. 12.], shape=(5), dtype=float32)

op_split(x, array(c(3)))

## [[1]]
## tf.Tensor([1. 2.], shape=(2), dtype=float32)
##
## [[2]]
## tf.Tensor([ 3.  4.  5.  6.  7.  8.  9. 10. 11. 12.], shape=(10), dtype=float32)
```

op_sqrt *Return the non-negative square root of a tensor, element-wise.*

---

## Description

Return the non-negative square root of a tensor, element-wise.

## Usage

```
op_sqrt(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, the non-negative square root of x.

`op_square` *Return the element-wise square of the input.*

---

## Description

Return the element-wise square of the input.

## Usage

```
op_square(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor, the square of x.

`op_squareplus` *Squareplus activation function.*

---

## Description

The Squareplus activation function is defined as:

`f(x) = (x + sqrt(x^2 + b)) / 2`

## Usage

```
op_squareplus(x, b = 4L)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| b | Smoothness parameter. Defaults to 4. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1.0, 0.0, 1.0))
op_squareplus(x)
```

```
## tf.Tensor([0.618034 1.       1.618034], shape=(3), dtype=float32)
```

op_squeeze *Remove axes of length one from* x.

---

## Description

Remove axes of length one from `x`.

## Usage

```
op_squeeze(x, axis = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis` | Select a subset of the entries of length one in the shape. |

## Value

The input tensor with all or a subset of the dimensions of length 1 removed.

---

`op_stack` *Join a sequence of tensors along a new axis.*

---

## Description

The `axis` parameter specifies the index of the new axis in the dimensions of the result.

## Usage

```
op_stack(x, axis = 1L)
```

## Arguments

| | |
|---|---|
| x | A sequence of tensors. |
| axis | Axis along which to stack. Defaults to 1, the first axis. |

## Value

The stacked tensor.

`op_std` *Compute the standard deviation along the specified axis.*

---

## Description

Compute the standard deviation along the specified axis.

## Usage

```
op_std(x, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis along which to compute standard deviation. Default is to compute the standard deviation of the flattened tensor. |
| keepdims | If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. |

## Value

Output tensor containing the standard deviation values.

`op_stft` *Short-Time Fourier Transform along the last axis of the input.*

---

## Description

The STFT computes the Fourier transform of short overlapping windows of the input. This giving frequency components of the signal as they change over time.

## Usage

```
op_stft(
```

```
  x,
  sequence_length,
  sequence_stride,
  fft_length,
  window = "hann",
  center = TRUE
)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| sequence_length | An integer representing the sequence length. |
| sequence_stride | An integer representing the sequence hop size. |
| fft_length | An integer representing the size of the FFT to apply. If not specified, uses the smallest power of 2 enclosing sequence_length. |
| window | A string, a tensor of the window or NULL. If window is a string, available values are "hann" and "hamming". If window is a tensor, it will be used directly as the window and its length must be sequence_length. If window is NULL, no windowing is used. Defaults to "hann". |
| center | Whether to pad x on both sides so that the t-th sequence is centered at time t * sequence_stride. Otherwise, the t-th sequence begins at time t * sequence_stride. Defaults to TRUE. |

## Value

A list containing two tensors - the real and imaginary parts of the STFT output.

## Examples

```
x <- op_array(c(0, 1, 2, 3, 4))
op_stft(x, 3, 2, 3)
```

```
## [[1]]
## tf.Tensor(
## [[ 0.  0.]
##  [ 2. -1.]
##  [ 4. -2.]], shape=(3, 2), dtype=float32)
##
## [[2]]
## tf.Tensor(
## [[ 0.         0.       ]
##  [ 0.        -1.7320508]
##  [ 0.        -3.4641016]], shape=(3, 2), dtype=float32)
```

op_stop_gradient *Stops gradient computation.*

---

## Description

Stops gradient computation.

## Usage

```
op_stop_gradient(variable)
```

## Arguments

| | |
|---|---|
| variable | A tensor variable for which the gradient computation is to be disabled. |

## Value

The variable with gradient computation disabled.

## Examples

```
var <- op_convert_to_tensor(c(1, 2, 3), dtype="float32")
var <- op_stop_gradient(var)
```

`op_subset` *Subset elements from a tensor*

---

## Description

Extract elements from a tensor using common R-style `[` indexing idioms. This function can also be conveniently accessed via the syntax `tensor@r[...]`.

## Usage

```
op_subset(x, ...)

op_subset(x, ...) <- value

op_subset_set(x, ..., value)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `...` | Indices specifying elements to extract. Each argument in `...` can be:<br>• An integer scalar<br>• A 1-d integer or logical vector<br>• `NULL` or `newaxis`<br>• The `..` symbol<br>• A slice expression using `:`<br>If only a single argument is supplied to `...`, then `..1` can also be:<br>• A logical array with the same shape as `x`<br>• An integer matrix where `ncol(..1) == op_rank(x)` |
| `value` | new value to replace the selected subset with. |

## Details

While the semantics are similar to R's `[`, there are some differences:

## Value

A tensor containing the subset of elements.

## Differences from R's `[`:

- Negative indices follow Python-style indexing, counting from the end of the array.
- `NULL` or `newaxis` adds a new dimension (equivalent to `op_expand_dims()`).
- If fewer indices than dimensions (`op_rank(x)`) are provided, missing dimensions are implicitly filled. For example, if `x` is a matrix, `x[1]` returns the first row.
- `..` or `all_dims()` expands to include all unspecified dimensions (see examples).
- Extended slicing syntax (`:`) is supported, including:
  - Strided steps: `x@r[start:end:step]`
  - `NA` values for `start` and `end`. `NA` for `start` defaults to `1`, and `NA` for `end` defaults to the axis size.
- A logical array matching the shape of `x` selects elements in row-wise order.

## Similarities with R's `[`:

Similarities to R's `[` (differences from Python's `[`):

- Positive indices are 1-based.
- Slices (`x[start:end]`) are inclusive of `end`.
- 1-d logical/integer arrays subset along their respective axis. Multiple vectors provided for different axes return intersected subsets.
- A single integer matrix with `ncol(i) == op_rank(x)` selects elements by coordinates. Each row in the matrix specifies the location of one value, where each column corresponds to an axis in the tensor being subsetted. This means you use a 2-column matrix to subset a matrix, a 3-column matrix to subset a 3d array, and so on.

## Examples

```
(x <- op_arange(5L) + 10L)

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

# Basic example, get first element
op_subset(x, 1)

## tf.Tensor(11, shape=(), dtype=int32)
```

```
# Use `@r[` syntax
x@r[1]           # same as `op_subset(x, 1)`

## tf.Tensor(11, shape=(), dtype=int32)

x@r[1:2]         # get the first 2 elements

## tf.Tensor([11 12], shape=(2), dtype=int32)

x@r[c(1, 3)]     # first and third element

## tf.Tensor([11 13], shape=(2), dtype=int32)

# Negative indices
x@r[-1]          # last element

## tf.Tensor(15, shape=(), dtype=int32)

x@r[-2]          # second to last element

## tf.Tensor(14, shape=(), dtype=int32)

x@r[c(-1, -2)]   # last and second to last elements

## tf.Tensor([15 14], shape=(2), dtype=int32)

x@r[c(-2, -1)]   # second to last and last elements

## tf.Tensor([14 15], shape=(2), dtype=int32)

x@r[c(1, -1)]    # first and last elements

## tf.Tensor([11 15], shape=(2), dtype=int32)

# Slices
x@r[1:3]          # first 3 elements

## tf.Tensor([11 12 13], shape=(3), dtype=int32)
```

```
x@r[NA:3]         # first 3 elements

## tf.Tensor([11 12 13], shape=(3), dtype=int32)

x@r[1:5]          # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[1:-1]         # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[NA:NA]        # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[]             # all elements

## tf.Tensor([11 12 13 14 15], shape=(5), dtype=int32)

x@r[1:-2]         # drop last element

## tf.Tensor([11 12 13 14], shape=(4), dtype=int32)

---

`op_subtract` *Subtract arguments element-wise.*

---

## Description

Note that this function is automatically called when using the R operator `-` with a tensor.

```
x <- op_ones(c(3))
op_subtract(x, x)

## tf.Tensor([0. 0. 0.], shape=(3), dtype=float32)

x - x

## tf.Tensor([0. 0. 0.], shape=(3), dtype=float32)
```

## Usage

```
op_subtract(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. |
| x2 | Second input tensor. |

## Value

Output tensor, element-wise difference of x1 and x2.

op_sum *Sum of a tensor over the given axes.*

---

## Description

Sum of a tensor over the given axes.

## Usage

```
op_sum(x, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis or axes along which the sum is computed. The default is to compute the sum of the flattened tensor. |
| keepdims | If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. |

## Value

Output tensor containing the sum.

op_svd *Computes the singular value decomposition of a matrix.*

---

## Description

Computes the singular value decomposition of a matrix.

## Usage

```
op_svd(x, full_matrices = TRUE, compute_uv = TRUE)
```

## Arguments

| | |
|---|---|
| x | Input tensor of shape (..., M, N). |
| full_matrices | Logical |
| compute_uv | Logical |

## Value

A list of three tensors:

- a tensor of shape (..., M, M) containing the left singular vectors,
- a tensor of shape (..., M, N) containing the singular values and
- a tensor of shape (..., N, N) containing the right singular vectors.

`op_swapaxes` *Interchange two axes of a tensor.*

---

## Description

Interchange two axes of a tensor.

## Usage

```
op_swapaxes(x, axis1, axis2)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axis1` | First axis. |
| `axis2` | Second axis. |

## Value

A tensor with the axes swapped.

---

`op_switch` *Apply exactly one of the* `branches` *given by* `index`.

---

## Description

If `index` is out of bounds, it is clamped to within bounds.

The semantics of `switch` are given roughly by this implementation:

```
op_switch <- function(index, branches, ...) {
  index <- op_clip(index, 1, length(branches))
  branches[[index]](...)
}
```

## Usage

```
op_switch(index, branches, ...)
```

## Arguments

| | |
|---|---|
| `index` | An integer scalar indicating which branch function to apply (1-based). |
| `branches` | A list of functions to be applied based on `index`. |
| `...` | Inputs to whichever branch is applied. |

## Value

The outputs of `branch(...)` for the branch that was selected based on `index`.

## Examples

```
add_fn <- function(x, y) x + y + 100
subtract_fn <- function(x, y) x - y - 100
x <- op_array(2)
y <- op_array(0.5)
branches <- list(add_fn, subtract_fn)
op_switch(0, branches, x, y) # +

## tf.Tensor(102.5, shape=(), dtype=float32)

op_switch(1, branches, x, y) # +

## tf.Tensor(102.5, shape=(), dtype=float32)

op_switch(2, branches, x, y) # -

## tf.Tensor(-98.5, shape=(), dtype=float32)

op_switch(3, branches, x, y) # -

## tf.Tensor(-98.5, shape=(), dtype=float32)
```

op_take *Take elements from a tensor along an axis.*

---

## Description

Take elements from a tensor along an axis.

## Usage

```
op_take(x, indices, axis = NULL, zero_indexed = FALSE)
```

## Arguments

| | |
|---|---|
| x | Source tensor. |
| indices | The indices of the values to extract. |
| axis | The axis over which to select values. By default, the flattened input tensor is used. |
| zero_indexed | If TRUE, treats indices as zero-based (0 encodes to first position); if FALSE (default), treats indices as one-based (1 encodes to first position). |

## Value

The corresponding tensor of values.

op_take_along_axis *Select values from* x *at the 1-D* indices *along the given axis.*

---

## Description

Select values from x at the 1-D indices along the given axis.

## Usage

```
op_take_along_axis(x, indices, axis = NULL, zero_indexed = FALSE)
```

## Arguments

| | |
|---|---|
| x | Source tensor. |
| indices | The indices of the values to extract. |
| axis | The axis over which to select values. By default, the flattened input tensor is used. |
| zero_indexed | If TRUE, treats indices as zero-based (0 encodes to first position); if FALSE (default), treats indices as one-based (1 encodes to first position). |

## Value

The corresponding tensor of values.

op_tan *Compute tangent, element-wise.*

---

## Description

Compute tangent, element-wise.

## Usage

```
op_tan(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor of same shape as x.

## See Also

op_tanh *Hyperbolic tangent, element-wise.*

---

## Description

Hyperbolic tangent, element-wise.

## Usage

```
op_tanh(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor of same shape as x.

op_tanh_shrink *Applies the tanh shrink function element-wise.*

## Description

It is defined as:

`f(x) = x - tanh(x)`.

## Usage

```
op_tanh_shrink(x)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |

## Value

Output tensor of the same shape as `x`, where each element is transformed according to the tanh shrink operation.

## Examples

```
x <- op_array(c(-1., 0., 1.))
op_tanh_shrink(x)
```

```
## tf.Tensor([-0.23840582  0.          0.23840582], shape=(3), dtype=float32)
```

`op_tensordot` *Compute the tensor dot product along specified axes.*

---

## Description

Compute the tensor dot product along specified axes.

## Usage

```
op_tensordot(x1, x2, axes = 3L)
```

## Arguments

| | |
|---|---|
| `x1` | First tensor. |
| `x2` | Second tensor. |
| `axes` | • If an integer, N, sum over the last N axes of `x1` and the first N axes of `x2` in order. The sizes of the corresponding axes must match.<br>• Or, a list of axes to be summed over, first sequence applying to `x1`, second to `x2`. Both sequences must be of the same length. |

## Value

The tensor dot product of the inputs.

`op_threshold` *Threshold activation function.*

---

## Description

The function thresholds the input `x` as follows: `f(x)` = `x` if `x` > `threshold`, `f(x)` = `default_value` otherwise.

## Usage

```
op_threshold(x, threshold, default_value)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `threshold` | The value that decides when to retain or replace x. |
| `default_value` | Value to assign when `x` <= `threshold`. |

## Value

A tensor with the same shape as `x`.

## Examples

```
x <- op_array(c(-1.0, 0.0, 1.0, 2.0))
op_threshold(x, 1, 0)

## tf.Tensor([0. 0. 0. 2.], shape=(4), dtype=float32)
```

---

op_tile *Repeat* x *the number of times given by* repeats.

---

## Description

If repeats has length d, the result will have dimension of max(d, x.ndim).

If x.ndim < d, x is promoted to be d-dimensional by prepending new axes.

If x.ndim > d, repeats is promoted to x.ndim by prepending 1's to it.

## Usage

```
op_tile(x, repeats)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| repeats | The number of repetitions of x along each axis. |

## Value

The tiled output tensor.

op_zeros_like()

---

op_top_k *Finds the top-k values and their indices in a tensor.*

---

## Description

Finds the top-k values and their indices in a tensor.

## Usage

```
op_top_k(x, k, sorted = TRUE, zero_indexed = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| k | An integer representing the number of top elements to retrieve. |
| sorted | A boolean indicating whether to sort the output in descending order. Defaults to TRUE. |
| zero_indexed | If TRUE, the returned indices are zero-based (0 encodes to first position); if FALSE (default), the returned indices are one-based (1 encodes to first position). |

## Value

A list containing two tensors. The first tensor contains the top-k values, and the second tensor contains the indices of the top-k values in the input tensor.

## Examples

```
x <- op_array(c(5, 2, 7, 1, 9, 3), "int32")
op_top_k(x, k = 3)
```

```
## $values
## tf.Tensor([9 7 5], shape=(3), dtype=int32)
##
## $indices
## tf.Tensor([5 3 1], shape=(3), dtype=int32)
```

```
c(values, indices) %<-% op_top_k(x, k = 3)
values
```

```
## tf.Tensor([9 7 5], shape=(3), dtype=int32)
```

```
indices
```

```
## tf.Tensor([5 3 1], shape=(3), dtype=int32)
```

---

`op_trace` *Return the sum along diagonals of the tensor.*

---

## Description

If `x` is 2-D, the sum along its diagonal with the given offset is returned, i.e., the sum of elements `x[i, i+offset]` for all `i`.

If a has more than two dimensions, then the axes specified by `axis1` and `axis2` are used to determine the 2-D sub-arrays whose traces are returned.

The shape of the resulting tensor is the same as that of `x` with `axis1` and `axis2` removed.

## Usage

```
op_trace(x, offset = 0L, axis1 = 1L, axis2 = 2L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `offset` | Offset of the diagonal from the main diagonal. Can be both positive and negative. Defaults to `0`. |
| `axis1` | Axis to be used as the first axis of the 2-D sub-arrays. Defaults to `1`. (first axis). |
| `axis2` | Axis to be used as the second axis of the 2-D sub-arrays. Defaults to `2`. (second axis). |

## Value

If `x` is 2-D, the sum of the diagonal is returned. If `x` has larger dimensions, then a tensor of sums along diagonals is returned.

`op_transpose` *Returns a tensor with* `axes` *transposed.*

---

## Description

Returns a tensor with `axes` transposed.

## Usage

```
op_transpose(x, axes = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `axes` | Sequence of integers. Permutation of the dimensions of `x`. By default, the order of the axes are reversed. |

## Value

`x` with its axes permuted.

---

`op_tri` *Return a tensor with ones at and below a diagonal and zeros elsewhere.*

---

## Description

Return a tensor with ones at and below a diagonal and zeros elsewhere.

## Usage

```
op_tri(N, M = NULL, k = 0L, dtype = NULL)
```

## Arguments

| | |
|---|---|
| `N` | Number of rows in the tensor. |
| `M` | Number of columns in the tensor. |
| `k` | The sub-diagonal at and below which the array is filled. `k = 0` is the main diagonal, while `k < 0` is below it, and `k > 0` is above. The default is 0. |
| `dtype` | Data type of the returned tensor. The default is "float32". |

## Value

Tensor with its lower triangle filled with ones and zeros elsewhere. `T[i, j] == 1` for `j <= i + k`, 0 otherwise.

---

`op_tril` *Return lower triangle of a tensor.*

---

## Description

For tensors with `ndim` exceeding 2, `tril` will apply to the final two axes.

## Usage

```
op_tril(x, k = 0L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `k` | Diagonal above which to zero elements. Defaults to `0`. the main diagonal. `k < 0` is below it, and `k > 0` is above it. |

## Value

Lower triangle of `x`, of same shape and data type as `x`.

---

## Description

For tensors with `ndim` exceeding 2, `triu` will apply to the final two axes.

## Usage

```
op_triu(x, k = 0L)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `k` | Diagonal below which to zero elements. Defaults to `0`. the main diagonal. `k < 0` is below it, and `k > 0` is above it. |

## Value

Upper triangle of `x`, of same shape and data type as `x`.

---

`op_trunc` *Return the truncated value of the input, element-wise.*

---

## Description

The truncated value of the scalar `x` is the nearest integer `i` which is closer to zero than `x` is. In short, the fractional part of the signed number `x` is discarded.

## Usage

```
op_trunc(x)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |

## Value

The truncated value of each element in `x`.

## Examples

```
x <- op_array(c(-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0))
op_trunc(x)

## tf.Tensor([-1. -1. -0.  0.  1.  1.  2.], shape=(7), dtype=float32)
```

---

`op_unravel_index` *Convert flat indices to coordinate arrays in a given array shape.*

---

## Description

Convert flat indices to coordinate arrays in a given array shape.

## Usage

```
op_unravel_index(indices, shape)
```

## Arguments

| | |
|---|---|
| `indices` | An integer or array of integers representing flat indices. |
| `shape` | The shape of the array to unravel into. |

## Value

Tuple of arrays for each dimension with unraveled indices.

## Examples

```
indices <- c(1, 5)
shape <- array(c(3, 3))
op_unravel_index(indices, shape)

## [[1]]
## tf.Tensor([0 1], shape=(2), dtype=int32)
##
## [[2]]
## tf.Tensor([0 1], shape=(2), dtype=int32)
```

op_unstack *Unpacks the given dimension of a rank-R tensor into rank-(R-1) tensors.*

---

## Description

Unpacks the given dimension of a rank-R tensor into rank-(R-1) tensors.

## Usage

```
op_unstack(x, num = NULL, axis = 1L)
```

## Arguments

| | |
|---|---|
| x | The input tensor. |
| num | The length of the dimension axis. Automatically inferred if NULL. |
| axis | The axis along which to unpack. |

## Value

A list of tensors unpacked along the given axis.

## Examples

```
x <- op_array(rbind(c(1, 2),
                    c(3, 4)))
op_unstack(x, axis=1)

## [[1]]
## tf.Tensor([1. 2.], shape=(2), dtype=float64)
##
## [[2]]
## tf.Tensor([3. 4.], shape=(2), dtype=float64)
```

```
op_unstack(x, axis=2)

## [[1]]
## tf.Tensor([1. 3.], shape=(2), dtype=float64)
##
## [[2]]
## tf.Tensor([2. 4.], shape=(2), dtype=float64)

all.equal(op_unstack(x),
          op_unstack(x, axis = 1))

## [1] TRUE

all.equal(op_unstack(x, axis = -1),
          op_unstack(x, axis = 2))

## [1] TRUE

# [array([1, 2]), array([3, 4])]
```

[3, 4))]: R:3,%204))

## op_var *Compute the variance along the specified axes.*

---

## Description

Compute the variance along the specified axes.

## Usage

```
op_var(x, axis = NULL, keepdims = FALSE)
```

## Arguments

| | |
|---|---|
| x | Input tensor. |
| axis | Axis or axes along which the variance is computed. The default is to compute the variance of the flattened tensor. |
| keepdims | If this is set to TRUE, the axes which are reduced are left in the result as dimensions with size one. |

## Value

Output tensor containing the variance.

---

op_vdot *Return the dot product of two vectors.*

---

## Description

If the first argument is complex, the complex conjugate of the first argument is used for the calculation of the dot product.

Multidimensional tensors are flattened before the dot product is taken.

## Usage

```
op_vdot(x1, x2)
```

## Arguments

| | |
|---|---|
| x1 | First input tensor. If complex, its complex conjugate is taken before calculation of the dot product. |
| x2 | Second input tensor. |

## Value

Output tensor.

`op_vectorize` *Turn a function into a vectorized function.*

---

## Description

Turn a function into a vectorized function.

## Usage

```
op_vectorize(func, ..., excluded = NULL, signature = NULL)
```

## Arguments

| | |
|---|---|
| func | Callable of a single tensor argument. |
| ... | For forward/backward compatability. |
| excluded | Optional set of integers representing positional arguments for which the function will not be vectorized. These will be passed directly to func unmodified. |
| signature | Optional generalized universal function signature, e.g., "(m,n),(n)->(m)" for vectorized matrix-vector multiplication. If provided, func will be called with (and expected to return) arrays with shapes given by the size of corresponding core dimensions. By default, func is assumed to take scalar tensors as input and output. |

## Value

A new function that applies func to every element of its input along axis 1 (the batch axis, the first axis).

## Examples

```
# currently does not work w/ tensorflow backend
if(config_backend() != "tensorflow") {

  myfunc <- function(a, b) a + b

  vfunc <- op_vectorize(myfunc)
  y <- vfunc(c(1, 2, 3, 4), 2)
  print(y)
  # with Jax backend, y is:
  # Array([3., 4., 5., 6.], dtype=float32)
}
```

op_vectorized_map *Parallel map of function* f *on the first axis of tensor(s)* elements.

---

## Description

Schematically, op_vectorized_map() maps over the first dimension of the provided tensors. If elements is a list of tensors, then each of the tensors are required to have the same size first dimension, and they are iterated over together.

## Usage

```
op_vectorized_map(elements, f)
```

## Arguments

| | |
|---|---|
| elements | see description |
| f | A function taking either a tensor, or list of tensors. |

## Value

A tensor or list of tensors, the result of mapping f across elements.

## Examples

```
(x <- op_arange(12L) |> op_reshape(c(3, 4)))

## tf.Tensor(
## [[ 1  2  3  4]
##  [ 5  6  7  8]
##  [ 9 10 11 12]], shape=(3, 4), dtype=int32)

x |> op_vectorized_map(\(row) {row + 10})
```

```
## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)

list(x, x, x) |> op_vectorized_map(\(rows) Reduce(`+`, rows))

## tf.Tensor(
## [[ 3  6  9 12]
##  [15 18 21 24]
##  [27 30 33 36]], shape=(3, 4), dtype=int32)
```

Note that `f` may be traced and compiled. Meaning, the R function may only evaluated once with symbolic tensors if using Jax or TensorFlow backends, and not with eager tensors. See the output from `str()` in these examples:

```
# simplest case, map f over rows of x,
# where .x is 1 row of x
input <- x
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  .x + 10
})

## <tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>

output

## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)

# map f over two tensors simultaneously. Here, # `.x` is a list of two
# tensors. The return values from each call of `f(row)` are stacked to form the
# final output
input <- list(x, x)
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  .x[[1]] + 10
})

## List of 2
##  $ :<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ :<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>
```

```
output

## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)

# same as above, but now returning two tensors in the final output
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  c(.x1, .x2) %<-% .x
  list(.x1+10, .x2+20)
})

## List of 2
##  $ :<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ :<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>

output

## [[1]]
## tf.Tensor(
## [[11 12 13 14]

##  [25 26 27 28]
##  [29 30 31 32]], shape=(3, 4), dtype=int32)
```

```
# passing a tuple() is equivalent to passing an unnamed list()
input <- tuple(x, x)
output <- op_vectorized_map(input, function(.x) {
  str(.x)
  list(.x[[1]] + 10)
})
```

```
## List of 2
##  $ :<tf.Tensor 'loop_body/GatherV2:0' shape=(4) dtype=int32>
##  $ :<tf.Tensor 'loop_body/GatherV2_1:0' shape=(4) dtype=int32>
```

```
output
```

```
## [[1]]
## tf.Tensor(
## [[11 12 13 14]
##  [15 16 17 18]
##  [19 20 21 22]], shape=(3, 4), dtype=int32)
```

## Debugging `f`

Even in eager contexts, `op_vectorized_map()` may trace `f`. In that case, if you want to eagerly debug `f` (e.g., with `browser()`), you can swap in a manual (slow) implementation of `op_vectorized_map()`. Note this example debug implementation does not handle all the same edge cases as `op_vectorized_map()`, in particular, if `f` returns a structure of multiple tensors.

```
op_vectorized_map_debug <- function(elements, fn) {

  if (!is.list(elements)) {
    # `elements` is a single tensor
    batch_size <- op_shape(elements)[[1]]
```

```
    out <- elements |>
      op_split(batch_size) |>
      lapply(fn) |>
      op_stack()
    return(out)
  }

  # `elements` is a list of tensors
  batch_size <- elements[[1]] |> op_shape() |> _[[1]]
  elements |>
    lapply(\(e) op_split(e, batch_size)) |>
    zip_lists() |>

---

`op_view_as_complex` *Convert a real tensor with two channels into a complex tensor.*

---

## Description

Expects a real-valued tensor whose last dimension has size 2, holding the real and imaginary parts. Returns the corresponding complex tensor with the last dimension removed.

## Usage

```
op_view_as_complex(x)
```

## Arguments

| | |
|---|---|
| x | Real-valued tensor whose trailing dimension encodes the complex components. |

## Value

A complex tensor with shape `op_shape(x)[-length(op_shape(x))]`.

## Examples

```
x <- op_array(matrix(c(1, 2, 3, 4), nrow = 2, byrow = TRUE))
op_view_as_complex(x)

## tf.Tensor([1.+2.j 3.+4.j], shape=(2), dtype=complex64)
```

---

`op_view_as_real` *Convert a complex tensor into a stacked real representation.*

---

## Description

Produces a real-valued tensor where the last dimension gathers the real and imaginary parts of the complex input.

## Usage

```
op_view_as_real(x)
```

## Arguments

| | |
|---|---|
| x | Complex-valued tensor to be converted. |

## Value

A real tensor with shape `c(op_shape(x), 2)` containing real and imaginary parts.

## Examples

```
x <- op_array(matrix(c(1, 2, 3, 4), nrow = 2, byrow = TRUE))
z <- op_view_as_complex(x)
op_view_as_real(z)

## tf.Tensor(
## [[1. 2.]
##  [3. 4.]], shape=(2, 2), dtype=float32)
```

op_vstack *Stack tensors in sequence vertically (row wise).*

---

## Description

Stack tensors in sequence vertically (row wise).

## Usage

```
op_vstack(xs, ...)
```

## Arguments

| | |
|---|---|
| xs, ... | Sequence of tensors. |

## Value

Tensor formed by stacking the given tensors.

## See Also

`op_where` *Return elements chosen from* `x1` *or* `x2` *depending on* `condition`.

---

## Description

Return elements chosen from `x1` or `x2` depending on `condition`.

## Usage

```
op_where(condition, x1 = NULL, x2 = NULL)
```

## Arguments

| | |
|---|---|
| condition | Where TRUE, yield x1, otherwise yield x2. |
| x1 | Values from which to choose when condition is TRUE. |
| x2 | Values from which to choose when condition is FALSE. |

## Value

A tensor with elements from x1 where condition is TRUE, and elements from x2 where condition is FALSE.

`op_while_loop` *While loop implementation.*

---

## Description

While loop implementation.

## Usage

```
op_while_loop(cond, body, loop_vars, maximum_iterations = NULL)
```

## Arguments

| | |
|---|---|
| cond | A callable that represents the termination condition of the loop. Must accept a loop_vars like structure as an argument. If loop_vars is a tuple or unnamed list, each element of loop_vars will be passed positionally to the callable. |
| body | A callable that represents the loop body. Must accept a loop_vars like structure as an argument, and return update value with the same structure. If loop_vars is a tuple or unnamed list, each element of loop_vars will be passed positionally to the callable. |
| loop_vars | An arbitrary nested structure of tensor state to persist across loop iterations. |
| maximum_iterations | Optional maximum number of iterations of the while loop to run. If provided, the cond output is AND-ed with an additional condition ensuring the number of iterations executed is no greater than maximum_iterations. |

## Value

A list of tensors, has the same shape and dtype as loop_vars.

## Examples

```
i <- 0
loop_vars <- list(i)

# cond() must return a scalar bool
cond <- function(i) i < 10L

# body must return same shape as loop_vars
body <- function(i) list(i + 1L)

op_while_loop(cond, body, loop_vars)

## [[1]]
## tf.Tensor(10.0, shape=(), dtype=float32)

x <- 0; y <- 1
cond <- \(x, y) x < 10
body <- \(x, y) list(x+1, y+1)
op_while_loop(cond, body, list(x, y))

## [[1]]
## tf.Tensor(10.0, shape=(), dtype=float32)
##
## [[2]]
## tf.Tensor(11.0, shape=(), dtype=float32)
```

---

`op_zeros` *Return a new tensor of given shape and type, filled with zeros.*

---

## Description

Return a new tensor of given shape and type, filled with zeros.

## Usage

```
op_zeros(shape, dtype = NULL)
```

## Arguments

| | |
|---|---|
| `shape` | Shape of the new tensor. |
| `dtype` | Desired data type of the tensor. |

## Value

Tensor of zeros with the given shape and dtype.

`op_zeros_like` *Return a tensor of zeros with the same shape and type as* `x`.

---

## Description

Return a tensor of zeros with the same shape and type as `x`.

## Usage

```
op_zeros_like(x, dtype = NULL)
```

## Arguments

| | |
|---|---|
| `x` | Input tensor. |
| `dtype` | Overrides the data type of the result. |

## Value

A tensor of zeros with the same shape and type as `x`.

pad_sequences *Pads sequences to the same length.*

---

## Description

This function transforms a list (of length num_samples) of sequences (lists of integers) into a 2D NumPy array of shape (num_samples, num_timesteps). num_timesteps is either the maxlen argument if provided, or the length of the longest sequence in the list.

Sequences that are shorter than num_timesteps are padded with value until they are num_timesteps long.

Sequences longer than num_timesteps are truncated so that they fit the desired length.

The position where padding or truncation happens is determined by the arguments padding and truncating, respectively. Pre-padding or removing values from the beginning of the sequence is the default.

```
sequence <- list(c(1), c(2, 3), c(4, 5, 6))
pad_sequences(sequence)
```

```
##      [,1] [,2] [,3]
## [1,]    0    0    1
## [2,]    0    2    3
## [3,]    4    5    6
```

```
pad_sequences(sequence, value=-1)
```

```
##      [,1] [,2] [,3]
## [1,]   -1   -1    1
## [2,]   -1    2    3
## [3,]    4    5    6
```

```
pad_sequences(sequence, padding='post')
```

```
##      [,1] [,2] [,3]
## [1,]    1    0    0
## [2,]    2    3    0
## [3,]    4    5    6
```

```
pad_sequences(sequence, maxlen=2)
```

```
##      [,1] [,2]
## [1,]    0    1
## [2,]    2    3
## [3,]    5    6
```

## Usage

```
pad_sequences(
  sequences,
  maxlen = NULL,
  dtype = "int32",
  padding = "pre",
  truncating = "pre",
  value = 0
)
```

## Arguments

| | |
|---|---|
| sequences | List of sequences (each sequence is a list of integers). |
| maxlen | Optional Int, maximum length of all sequences. If not provided, sequences will be padded to the length of the longest individual sequence. |
| dtype | (Optional, defaults to "int32"). Type of the output sequences. To pad sequences with variable length strings, you can use object. |
| padding | String, "pre" or "post" (optional, defaults to "pre"): pad either before or after each sequence. |
| truncating | String, "pre" or "post" (optional, defaults to "pre"): remove values from sequences larger than maxlen, either at the beginning or at the end of the sequences. |
| value | Float or String, padding value. (Optional, defaults to 0) |

## Value

Array with shape `(len(sequences), maxlen)`

# plot.keras.src.models.model.Model

*Plot a Keras model*

---

## Description

Plot a Keras model

## Usage

```
## S3 method for class 'keras.src.models.model.Model'
plot(
  x,
```

```
  show_shapes = FALSE,
  show_dtype = FALSE,
  show_layer_names = FALSE,
  ...,
  rankdir = "TB",
  expand_nested = FALSE,
  dpi = getOption("keras.plot.model.dpi", 200L),
  layer_range = NULL,
  show_layer_activations = FALSE,
  show_trainable = NA,
  to_file = NULL
)
```

## Arguments

| | |
|---|---|
| x | A Keras model instance |
| show_shapes | whether to display shape information. |
| show_dtype | whether to display layer dtypes. |
| show_layer_names | whether to display layer names. |
| ... | passed on to Python `keras.utils.model_to_dot()`. Used for forward and backward compatibility. |
| rankdir | a string specifying the format of the plot: `'TB'` creates a vertical plot; `'LR'` creates a horizontal plot. (argument passed to PyDot) |
| expand_nested | Whether to expand nested models into clusters. |
| dpi | Dots per inch. Increase this value if the image text appears excessively pixelated. |
| layer_range | `list` containing two character strings, which is the starting layer name and ending layer name (both inclusive) indicating the range of layers for which the plot will be generated. It also accepts regex patterns instead of exact name. In such case, start predicate will be the first element it matches to `layer_range[1]` and the end predicate will be the last element it matches to `layer_range[2]`. By default `NULL` which considers all layers of model. Note that you must pass range such that the resultant subgraph must be complete. |
| show_layer_activations | Display layer activations (only for layers that have an `activation` property). |
| show_trainable | whether to display if a layer is trainable. |
| to_file | File name of the plot image. If `NULL` (the default), the model is drawn on the default graphics device. Otherwise, a file is saved. |

## Value

Nothing, called for it side effects.

## Raises

ValueError: if `plot(model)` is called before the model is built, unless an `input_shape =` argument was supplied to `keras_model_sequential()`.

## Requirements

This function requires pydot and graphviz.

pydot is by default installed by `install_keras()`, but if you installed Keras by other means, you can install pydot directly with:

```
reticulate::py_install("pydot", pip = TRUE)
```

You can install graphviz directly from here: https://graphviz.gitlab.io/download/

On most Linux platforms, can install graphviz via the package manager. For example, on Ubuntu/Debian you can install with

```
sudo apt install graphviz
```

On macOS you can install graphviz using brew:

```
brew install graphviz
```

In a conda environment, you can install graphviz with:

```
reticulate::conda_install(packages = "graphviz")
# Restart the R session after install.
```

---

`plot.keras_training_history` *Plot training history*

---

## Description

Plots metrics recorded during training.

## Usage

```
## S3 method for class 'keras_training_history'
plot(
  x,
  y,
  metrics = NULL,
  method = c("auto", "ggplot2", "base"),
  smooth = getOption("keras.plot.history.smooth", TRUE),
  theme_bw = getOption("keras.plot.history.theme_bw", FALSE),
  ...
)
```

### Arguments

| | |
|---|---|
| x | Training history object returned from fit.keras.src.models.model.Model(). |
| y | Unused. |
| metrics | One or more metrics to plot (e.g. c('loss', 'accuracy')). Defaults to plotting all captured metrics. |
| method | Method to use for plotting. The default "auto" will use **ggplot2** if available, and otherwise will use base graphics. |
| smooth | Whether a loess smooth should be added to the plot, only available for the ggplot2 method. If the number of epochs is smaller than ten, it is forced to false. |
| theme_bw | Use ggplot2::theme_bw() to plot the history in black and white. |
| ... | Additional parameters to pass to the plot() method. |

### Value

if method == "ggplot2", the ggplot object is returned. If method == "base", then this function will draw to the graphics device and return NULL, invisibly.

---

## pop_layer *Remove the last layer in a Sequential model*

---

### Description

Remove the last layer in a Sequential model

### Usage

```
pop_layer(object, rebuild = TRUE)
```

### Arguments

| | |
|---|---|
| object | Sequential keras model object |
| rebuild | bool. Whether to rebuild the model after removing the layer. Defaults to TRUE. |

### Value

The removed layer.

## See Also

Other model functions:
get_config()
get_layer()
get_state_tree()
keras_model()
keras_model_sequential()
set_state_tree()
summary.keras.src.models.model.Model()

---

`predict.keras.src.models.model.Model`
*Generates output predictions for the input samples.*

---

## Description

Generates output predictions for the input samples.

## Usage

```
## S3 method for class 'keras.src.models.model.Model'
predict(
  object,
  x,
  ...,
  batch_size = NULL,
  verbose = getOption("keras.verbose", default = "auto"),
  steps = NULL,
  callbacks = NULL
)
```

## Arguments

| | |
|---|---|
| `object` | Keras model object |
| `x` | Input samples. It can be:<br>• A array (or array-like), or a list of arrays (in case the model has multiple inputs).<br>• A backend-native tensor, or a list of tensors (in case the model has multiple inputs).<br>• A TF Dataset.<br>• A Python generator function. |
| `...` | For forward/backward compatability. |
| `batch_size` | Integer or `NULL`. Number of samples per batch of computation. If unspecified, `batch_size` will default to `32`. Do not specify the `batch_size` if your input data `x` is in the form of a TF Dataset or a generator (since they generate batches). |

| | |
|---|---|
| verbose | "auto", 0, 1, or 2. Verbosity mode. 0 = silent, 1 = progress bar, 2 = one line per epoch. "auto" becomes 1 for most cases, 2 if in a knitr render or running on a distributed training server. Note that the progress bar is not particularly useful when logged to a file, so verbose=2 is recommended when not running interactively (e.g., in a production environment). Defaults to "auto". |
| steps | Total number of steps (batches of samples) to draw before declaring the prediction round finished. If steps is NULL, predict() will run until x is exhausted. In the case of an infinitely repeating dataset, predict() will run indefinitely. |
| callbacks | List of Callback instances. List of callbacks to apply during prediction. |

## Details

Computation is done in batches. This method is designed for batch processing of large numbers of inputs. It is not intended for use inside of loops that iterate over your data and process small numbers of inputs at a time.

For small numbers of inputs that fit in one batch, directly call the model model$call for faster execution, e.g., model(x), or model(x, training = FALSE) if you have layers such as BatchNormalization that behave differently during inference.

## Value

R array(s) of predictions.

## Note

See this FAQ entry for more details about the difference between Model methods predict() and call().

evaluate.keras.src.models.model.Model()
predict_on_batch()
test_on_batch()
train_on_batch()

---

predict_on_batch *Returns predictions for a single batch of samples.*

---

## Description

Returns predictions for a single batch of samples.

### Usage

```
predict_on_batch(object, x)
```

### Arguments

| | |
|---|---|
| object | Keras model object |
| x | Input data. It must be array-like. |

### Value

Array(s) of predictions.

### See Also

- https://keras.io/api/models/model_training_apis#predictonbatch-method

Other model training:
compile.keras.src.models.model.Model()
evaluate.keras.src.models.model.Model()

test_on_batch()
train_on_batch()

---

## process_utils *Preprocessing and postprocessing utilities*

---

### Description

These functions are used to preprocess and postprocess inputs and outputs of Keras applications.

### Usage

```
application_preprocess_inputs(model, x, ..., data_format = NULL)

application_decode_predictions(model, preds, top = 5L, ...)
```

### Arguments

| | |
|---|---|
| model | A Keras model initialized using any application_ function. |
| x | A batch of inputs to the model. If x is missing, then the preprocess_input function appropriate for model is returned. |
| ... | Additional arguments passed to the preprocessing or decoding function. |
| data_format | Optional data format of the image tensor/array. NULL means the global setting config_image_data_format() is used (unless you changed it, it uses "channels_last"). Defaults to NULL. |
| preds | A batch of outputs from the model. |
| top | The number of top predictions to return. |

### Value

- A list of decoded predictions in case of `application_decode_predictions()`.
- A batch of preprocessed inputs in case of `application_preprocess_inputs()`.

### Functions

- `application_preprocess_inputs()`: Pre-process inputs to be used in the model
- `application_decode_predictions()`: Decode predictions from the model

### Examples

```
## Not run:
model <- application_convnext_tiny()

inputs <- random_normal(c(32, 224, 224, 3))
processed_inputs <- application_preprocess_inputs(model, inputs)

preds <- random_normal(c(32, 1000))
decoded_preds <- application_decode_predictions(model, preds)

## End(Not run)
```

---

## `quantize_weights` *Quantize the weights of a model.*

---

### Description

Note that the model must be built first before calling this method. `quantize_weights()` will recursively call `layer$quantize(mode)` in all layers and will be skipped if the layer doesn't implement the function.

Currently only `Dense` and `EinsumDense` layers support quantization.

### Usage

```
quantize_weights(object, mode, ...)
```

### Arguments

| | |
|---|---|
| `object` | A Keras Model or Layer. |
| `mode` | The mode of the quantization. Only 'int8' is supported at this time. |
| `...` | Passed on to the `object` quantization method. |

### Value

`model`, invisibly. Note this is just a convenience for usage with `|>`, the model is modified in-place.

## See Also

Other layer methods:
count_params()
get_config()
get_weights()
reset_state()

---

random_beta *Draw samples from a Beta distribution.*

---

## Description

The values are drawn from a Beta distribution parametrized by alpha and beta.

## Usage

```
random_beta(shape, alpha, beta, dtype = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| shape | The shape of the random values to generate. |
| alpha | Float or an array of floats representing the first parameter alpha. Must be broadcastable with beta and shape. |
| beta | Float or an array of floats representing the second parameter beta. Must be broadcastable with alpha and shape. |
| dtype | Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to "float32" unless you configured it otherwise (via config_set_floatx(float_dtype)). |
| seed | Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided. |

## Value

A tensor of random values.

## See Also

Other random:
random_binomial()
random_categorical()

---

`random_binomial` *Draw samples from a Binomial distribution.*

---

## Description

The values are drawn from a Binomial distribution with specified trial count and probability of success.

## Usage

```
random_binomial(shape, counts, probabilities, dtype = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| shape | The shape of the random values to generate. |
| counts | A number or array of numbers representing the number of trials. It must be broadcastable with probabilities. |
| probabilities | A float or array of floats representing the probability of success of an individual event. It must be broadcastable with counts. |
| dtype | Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to "float32" unless you configured it otherwise (via config_set_floatx(float_dtype)). |
| seed | Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided. |

## Value

A tensor of random values.

---

# random_categorical *Draws samples from a categorical distribution.*

---

## Description

This function takes as input `logits`, a 2-D input tensor with shape (batch_size, num_classes). Each row of the input represents a categorical distribution, with each column index containing the log-probability for a given class.

The function will output a 2-D tensor with shape (batch_size, num_samples), where each row contains samples from the corresponding row in `logits`. Each column index contains an independent samples drawn from the input distribution.

```
x <- matrix(c(100, .1, 99), nrow = 1)
random_categorical(x, num_samples = 5, seed = 1234)
```

```
## tf.Tensor([[3 1 1 3 3]], shape=(1, 5), dtype=int32)
```

```
random_categorical(x, num_samples = 5, seed = 1234,
                   zero_indexed = TRUE)
```

```
## tf.Tensor([[2 0 0 2 2]], shape=(1, 5), dtype=int32)
```

```
op_take(x, random_categorical(x, num_samples = 5, seed = 1234))
```

```
## tf.Tensor([[ 99. 100. 100.  99.  99.]], shape=(1, 5), dtype=float64)

op_take(x, random_categorical(x, num_samples = 5, seed = 1234,
                              zero_indexed = TRUE),
        zero_indexed = TRUE)

## tf.Tensor([[ 99. 100. 100.  99.  99.]], shape=(1, 5), dtype=float64)
```

## Usage

```
random_categorical(
  logits,
  num_samples,
  dtype = "int32",
  seed = NULL,
  zero_indexed = FALSE
)
```

## Arguments

| | |
|---|---|
| logits | 2-D Tensor with shape (batch_size, num_classes). Each row should define a categorical distribution with the unnormalized log-probabilities for all classes. |
| num_samples | Int, the number of independent samples to draw for each row of the input. This will be the second dimension of the output tensor's shape. |
| dtype | Optional dtype of the output tensor. |
| seed | Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided. |
| zero_indexed | If TRUE, the returned indices are zero-based (0 encodes to first position); if FALSE (default), the returned indices are one-based (1 encodes to first position). |

## Value

A 2-D tensor with (batch_size, num_samples).

## See Also

---

`random_dropout` *Randomly set some values in a tensor to 0.*

---

## Description

Randomly set some portion of values in the tensor to 0.

## Usage

```
random_dropout(inputs, rate, noise_shape = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| `inputs` | A tensor |
| `rate` | numeric |
| `noise_shape` | A `shape()` value |
| `seed` | Initial seed for the random number generator |

## Value

A tensor that is a copy of `inputs` with some values set to `0`.

## See Also

---

random_gamma *Draw random samples from the Gamma distribution.*

---

## Description

Draw random samples from the Gamma distribution.

## Usage

```
random_gamma(shape, alpha, dtype = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| shape | The shape of the random values to generate. |
| alpha | Float, the parameter of the distribution. |
| dtype | Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to float32 unless you configured it otherwise (via config_set_floatx(float_dtype)). |
| seed | Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided. |

## Value

---

`random_integer` *Draw random integers from a uniform distribution.*

---

## Description

The generated values follow a uniform distribution in the range `[minval, maxval)`. The lower bound `minval` is included in the range, while the upper bound `maxval` is excluded.

`dtype` must be an integer type.

## Usage

```
random_integer(shape, minval, maxval, dtype = "int32", seed = NULL)
```

## Arguments

| | |
|---|---|
| `shape` | The shape of the random values to generate. |
| `minval` | integer, lower bound of the range of random values to generate (inclusive). |
| `maxval` | integer, upper bound of the range of random values to generate (exclusive). |
| `dtype` | Optional dtype of the tensor. Only integer types are supported. If not specified, `"int32"` is used. |
| `seed` | Optional R integer or instance of `random_seed_generator()`. By default, the `seed` argument is `NULL`, and an internal global `random_seed_generator()` is used. The `seed` argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the `seed` value will produce the same random values for each call. To generate different random values for repeated calls, an instance of `random_seed_generator()` must be provided as the `seed` value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global `random_seed_generator()` is not supported. Therefore, during tracing the default value `seed=NULL` will produce an error, and a `seed` argument must be provided. |

## Value

A tensor of random values.

---

`random_normal` *Draw random samples from a normal (Gaussian) distribution.*

---

## Description

Draw random samples from a normal (Gaussian) distribution.

## Usage

```
random_normal(shape, mean = 0, stddev = 1, dtype = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| shape | The shape of the random values to generate. |
| mean | Float, defaults to 0. Mean of the random values to generate. |
| stddev | Float, defaults to 1. Standard deviation of the random values to generate. |
| dtype | Optional dtype of the tensor. Only floating point types are supported. If not specified, config_floatx() is used, which defaults to float32 unless you configured it otherwise (via config_set_floatx(float_dtype)). |
| seed | Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided. |

## Value

A tensor of random values.

## See Also

Other random:
random_beta()

random_categorical()
random_dropout()
random_gamma()
random_integer()
random_seed_generator()
random_shuffle()
random_truncated_normal()
random_uniform()

---

`random_seed_generator` *Generates variable seeds upon each call to a function generating random numbers.*

---

## Description

In Keras, all random number generators (such as `random_normal()`) are stateless, meaning that if you pass an integer seed to them (such as `seed=42`), they will return the same values for repeated calls. To get different values for each call, a `SeedGenerator` providing the state of the random generator has to be used.

Note that all the random number generators have a default seed of `NULL`, which implies that an internal global `SeedGenerator` is used. If you need to decouple the RNG from the global state you can provide a local `StateGenerator` with either a deterministic or random initial state.

Remark concerning the JAX backen: Note that the use of a local `StateGenerator` as seed argument is required for JIT compilation of RNG with the JAX backend, because the use of global state is not supported.

## Usage

```
random_seed_generator(seed = NULL, name = NULL, ...)
```

## Arguments

| | |
|---|---|
| `seed` | Initial seed for the random number generator |
| `name` | String, name for the object |
| `...` | For forward/backward compatability. |

## Value

A SeedGenerator instance, which can be passed as the seed = argument to other random tensor generators.

## Examples

```
seed_gen <- random_seed_generator(seed = 42)
values <- random_normal(shape = c(2, 3), seed = seed_gen)
new_values <- random_normal(shape = c(2, 3), seed = seed_gen)
```

Usage in a layer:

```
layer_dropout2 <- new_layer_class(
  "dropout2",
  initialize = function(...) {
    super$initialize(...)
    self$seed_generator <- random_seed_generator(seed = 1337)
  },
  call = function(x, training = FALSE) {
    if (training) {
      return(random_dropout(x, rate = 0.5, seed = self$seed_generator))
    }
    return(x)
  }
)

out <- layer_dropout(rate = 0.8)
out(op_ones(10), training = TRUE)

## tf.Tensor([0. 5. 5. 0. 0. 0. 0. 0. 0. 0.], shape=(10), dtype=float32)

random_shuffle *Shuffle the elements of a tensor uniformly at random along an axis.*

## Description

Shuffle the elements of a tensor uniformly at random along an axis.

## Usage

```
random_shuffle(x, axis = 1L, seed = NULL)
```

## Arguments

| | |
|---|---|
| x | The tensor to be shuffled. |
| axis | An integer specifying the axis along which to shuffle. Defaults to 0. |
| seed | Optional R integer or instance of random_seed_generator(). By default, the seed argument is NULL, and an internal global random_seed_generator() is used. The seed argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the seed value will produce the same random values for each call. To generate different random values for repeated calls, an instance of random_seed_generator() must be provided as the seed value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global random_seed_generator() is not supported. Therefore, during tracing the default value seed=NULL will produce an error, and a seed argument must be provided. |

## Value

A tensor, a copy of x with the axis axis shuffled.

`random_truncated_normal` *Draw samples from a truncated normal distribution.*

## Description

The values are drawn from a normal distribution with specified mean and standard deviation, discarding and re-drawing any samples that are more than two standard deviations from the mean.

## Usage

```
random_truncated_normal(shape, mean = 0, stddev = 1, dtype = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| shape | The shape of the random values to generate. |
| mean | Float, defaults to 0. Mean of the random values to generate. |
| stddev | Float, defaults to 1. Standard deviation of the random values to generate. |
| dtype | Optional dtype of the tensor. Only floating point types are supported. If not specified, `config_floatx()` is used, which defaults to `float32` unless you configured it otherwise (via `config_set_floatx(float_dtype)`) |
| seed | Optional R integer or instance of `random_seed_generator()`. By default, the `seed` argument is `NULL`, and an internal global `random_seed_generator()` is used. The `seed` argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the `seed` value will produce the same random values for each call. To generate different random values for repeated calls, an instance of `random_seed_generator()` must be provided as the `seed` value.<br>Remark concerning the JAX backend: When tracing functions with the JAX backend the global `random_seed_generator()` is not supported. Therefore, during tracing the default value `seed=NULL` will produce an error, and a `seed` argument must be provided. |

random_uniform()

---

random_uniform *Draw samples from a uniform distribution.*

---

## Description

The generated values follow a uniform distribution in the range `[minval, maxval)`. The lower bound `minval` is included in the range, while the upper bound `maxval` is excluded.

`dtype` must be a floating point type, the default range is `[0, 1)`.

## Usage

```
random_uniform(shape, minval = 0, maxval = 1, dtype = NULL, seed = NULL)
```

## Arguments

| | |
|---|---|
| shape | The shape of the random values to generate. |
| minval | Float, defaults to 0. Lower bound of the range of random values to generate (inclusive). |
| maxval | Float, defaults to 1. Upper bound of the range of random values to generate (exclusive). |
| dtype | Optional dtype of the tensor. Only floating point types are supported. If not specified, `config_floatx()` is used, which defaults to `float32` unless you configured it otherwise (via `config_set_floatx(float_dtype)`) |
| seed | Optional R integer or instance of `random_seed_generator()`. By default, the `seed` argument is `NULL`, and an internal global `random_seed_generator()` is used. The `seed` argument can be used to ensure deterministic (repeatable) random number generation. Note that passing an integer as the `seed` value will produce the same random values for each call. # register_keras_serializable

*Registers a custom object with the Keras serialization framework.*

---

## Description

This function registers a custom class or function with the Keras custom object registry, so that it can be serialized and deserialized without needing an entry in the user-provided custom_objects argument. It also injects a function that Keras will call to get the object's serializable string key.

Note that to be serialized and deserialized, classes must implement the get_config() method. Functions do not have this requirement.

The object will be registered under the key 'package>name' where name, defaults to the object name if not passed.

## Usage

```
register_keras_serializable(object, name = NULL, package = NULL)
```

## Arguments

| | |
|---|---|
| object | A keras object. |
| name | The name to serialize this class under in this package. |
| package | The package that this class belongs to. This is used for the key (which is "package>name") to identify the class. Defaults to the current package name, or "Custom" outside of a package. |

## Value

The registered object (and converted) is returned. This returned object is what you should must use when building and serializing the model.

## Examples

```
# Note that `'my_package'` is used as the `package` argument here, and since
# the `name` argument is not provided, `'MyDense'` is used as the `name`.
layer_my_dense <- Layer("MyDense")
layer_my_dense <-
  register_keras_serializable(layer_my_dense, package = "my_package")

MyDense <- environment(layer_my_dense)$`__class__` # the python class obj
stopifnot(exprs = {
  get_registered_object('my_package>MyDense') == MyDense
  get_registered_name(MyDense) == 'my_package>MyDense'
})
```

# regularizer_l1 *A regularizer that applies a L1 regularization penalty.*

---

## Description

The L1 regularization penalty is computed as: `loss = l1 * reduce_sum(abs(x))`

L1 may be passed to a layer as a string identifier:

```
dense <- layer_dense(units = 3, kernel_regularizer = 'l1')
```

In this case, the default value used is `l1=0.01`.

## Usage

```
regularizer_l1(l1 = 0.01)
```

## Arguments

| | |
|---|---|
| l1 | float, L1 regularization factor. |

## Value

A Regularizer instance that can be passed to layer constructors or used as a standalone object.

## See Also

- https://keras.io/api/layers/regularizers#l1-class

Other regularizers:
regularizer_l1_l2()
regularizer_l2()

---

# regularizer_l1_l2 *A regularizer that applies both L1 and L2 regularization penalties.*

---

## Description

The L1 regularization penalty is computed as: loss = l1 * reduce_sum(abs(x))

The L2 regularization penalty is computed as loss = l2 * reduce_sum(square(x))

L1L2 may be passed to a layer as a string identifier:

```
dense <- layer_dense(units = 3, kernel_regularizer = 'L1L2')
```

In this case, the default values used are l1=0.01 and l2=0.01.

## Usage

```
regularizer_l1_l2(l1 = 0, l2 = 0)
```

## Arguments

| | |
|---|---|
| l1 | float, L1 regularization factor. |
| l2 | float, L2 regularization factor. |

## Value

A Regularizer instance that can be passed to layer constructors or used as a standalone object.

Other regularizers:
regularizer_l1()
regularizer_l2()
regularizer_orthogonal()

---

regularizer_l2 *A regularizer that applies a L2 regularization penalty.*

---

## Description

The L2 regularization penalty is computed as: `loss = l2 * reduce_sum(square(x))`

L2 may be passed to a layer as a string identifier:

```
dense <- layer_dense(units = 3, kernel_regularizer='l2')
```

In this case, the default value used is `l2=0.01`.

## Usage

```
regularizer_l2(l2 = 0.01)
```

## Arguments

| | |
|---|---|
| l2 | float, L2 regularization factor. |

## Value

A `Regularizer` instance that can be passed to layer constructors or used as a standalone object.

## See Also

- https://keras.io/api/layers/regularizers#l2-class

Other regularizers:
regularizer_l1()
regularizer_l1_l2()
regularizer_orthogonal()

regularizer_orthogonal *Regularizer that encourages input vectors to be orthogonal to each other.*

## Description

It can be applied to either the rows of a matrix (`mode="rows"`) or its columns (`mode="columns"`). When applied to a `Dense` kernel of shape `(input_dim, units)`, rows mode will seek to make the feature vectors (i.e. the basis of the output space) orthogonal to each other.

## Usage

```
regularizer_orthogonal(factor = 0.01, mode = "rows")
```

## Arguments

| | |
|---|---|
| `factor` | Float. The regularization factor. The regularization penalty will be proportional to `factor` times the mean of the dot products between the L2-normalized rows (if `mode="rows"`, or columns if `mode="columns"`) of the inputs, excluding the product of each row/column with itself. Defaults to `0.01`. |
| `mode` | String, one of `{"rows", "columns"}`. Defaults to `"rows"`. In rows mode, the regularization effect seeks to make the rows of the input orthogonal to each other. In columns mode, it seeks to make the columns of the input orthogonal to each other. |

## Value

A `Regularizer` instance that can be passed to layer constructors or used as a standalone object.

## Examples

```
regularizer <- regularizer_orthogonal(factor=0.01)
layer <- layer_dense(units=4, kernel_regularizer=regularizer)
```

## reset_state *Reset the state for a model, layer or metric.*

### Description

Reset the state for a model, layer or metric.

### Usage

```
reset_state(object)
```

### Arguments

| | |
|---|---|
| object | Model, Layer, or Metric instance<br>Not all Layers have resettable state (E.g., adapt()-able preprocessing layers and rnn layers have resettable state, but a layer_dense() does not). Calling this on a Layer instance without any resettable-state will error. |

### Value

object, invisibly.

### See Also

count_params()
get_config()
get_weights()
quantize_weights()

## rnn_cells_stack *Wrapper allowing a stack of RNN cells to behave as a single cell.*

### Description

Used to implement efficient stacked RNNs.

### Usage

```
rnn_cells_stack(cells, ...)
```

### Arguments

| | |
|---|---|
| cells | List of RNN cell instances. |
| ... | Unnamed arguments are treated as additional cells. Named arguments are passed on to the underlying layer. |

## Value

A Layer instance, which is intended to be used with layer_rnn().

## Example

```
batch_size <- 3
sentence_length <- 5
num_features <- 2
new_shape <- c(batch_size, sentence_length, num_features)
x <- array(1:30, dim = new_shape)

rnn_cells <- lapply(1:2, function(x) rnn_cell_lstm(units = 128))
stacked_lstm <- rnn_cells_stack(rnn_cells)
lstm_layer <- layer_rnn(cell = stacked_lstm)

result <- lstm_layer(x)
str(result)

## <tf.Tensor: shape=(3, 128), dtype=float32, numpy=. . . >

`rnn_cell_gru` *Cell class for the GRU layer.*

---

## Description

This class processes one step within the whole time sequence input, whereas `layer_gru()` processes the whole sequence.

## Usage

```
rnn_cell_gru(
  units,
  activation = "tanh",
  recurrent_activation = "sigmoid",
  use_bias = TRUE,
  kernel_initializer = "glorot_uniform",
  recurrent_initializer = "orthogonal",
  bias_initializer = "zeros",
  kernel_regularizer = NULL,
```

```
  recurrent_regularizer = NULL,
  bias_regularizer = NULL,
  kernel_constraint = NULL,
  recurrent_constraint = NULL,
  bias_constraint = NULL,
  dropout = 0,
  recurrent_dropout = 0,
  reset_after = TRUE,
  seed = NULL,
  ...
)
```

## Arguments

| | |
|---|---|
| `units` | Positive integer, dimensionality of the output space. |
| `activation` | Activation function to use. Default: hyperbolic tangent (`tanh`). If you pass `NULL`, no activation is applied (ie. "linear" activation: `a(x) = x`). |
| `recurrent_activation` | Activation function to use for the recurrent step. Default: sigmoid (`sigmoid`). If you pass `NULL`, no activation is applied (ie. "linear" activation: `a(x) = x`). |
| `use_bias` | Boolean, (default `TRUE`), whether the layer should use a bias vector. |
| `kernel_initializer` | Initializer for the `kernel` weights matrix, used for the linear transformation of the inputs. Default: `"glorot_uniform"`. |
| `recurrent_initializer` | Initializer for the `recurrent_kernel` weights matrix, used for the linear transformation of the recurrent state. Default: `"orthogonal"`. |
| `bias_initializer` | Initializer for the bias vector. Default: `"zeros"`. |
| `kernel_regularizer` | Regularizer function applied to the `kernel` weights matrix. Default: `NULL`. |
| `recurrent_regularizer` | Regularizer function applied to the `recurrent_kernel` weights matrix. Default: `NULL`. |
| `bias_regularizer` | Regularizer function applied to the bias vector. Default: `NULL`. |
| `kernel_constraint` | Constraint function applied to the `kernel` weights matrix. Default: `NULL`. |
| `recurrent_constraint` | Constraint function applied to the `recurrent_kernel` weights matrix. Default: `NULL`. |
| `bias_constraint` | Constraint function applied to the bias vector. Default: `NULL`. |
| `dropout` | Float between 0 and 1. Fraction of the units to drop for the linear transformation of the inputs. Default: 0. |

recurrent_dropout
: Float between 0 and 1. Fraction of the units to drop for the linear transformation of the recurrent state. Default: 0.

reset_after
: GRU convention (whether to apply reset gate after or before matrix multiplication). FALSE = "before", TRUE = "after" (default and cuDNN compatible).

seed
: Random seed for dropout.

...
: For forward/backward compatability.

## Value

A Layer instance, which is intended to be used with layer_rnn().

## Call Arguments

- inputs: A 2D tensor, with shape (batch, features).
- states: A 2D tensor with shape (batch, units), which is the state from the previous time step.
- training: Python boolean indicating whether the layer should behave in training mode or in inference mode. Only relevant when dropout or recurrent_dropout is used.

## Examples

```
inputs <- random_uniform(c(32, 10, 8))
outputs <- inputs |> layer_rnn(rnn_cell_gru(4))
shape(outputs)

## shape(32, 4)

rnn <- layer_rnn(
   cell = rnn_cell_gru(4),
   return_sequences=TRUE,
   return_state=TRUE)
c(whole_sequence_output, final_state) %<-% rnn(inputs)
shape(whole_sequence_output)

## shape(32, 10, 4)

shape(final_state)

## shape(32, 4)
```

`rnn_cell_lstm` *Cell class for the LSTM layer.*

---

## Description

This class processes one step within the whole time sequence input, whereas `layer_lstm()` processes the whole sequence.

## Usage

```
rnn_cell_lstm(
  units,
  activation = "tanh",
  recurrent_activation = "sigmoid",
  use_bias = TRUE,
  kernel_initializer = "glorot_uniform",
  recurrent_initializer = "orthogonal",
  bias_initializer = "zeros",
  unit_forget_bias = TRUE,
  kernel_regularizer = NULL,
  recurrent_regularizer = NULL,
  bias_regularizer = NULL,
  kernel_constraint = NULL,
  recurrent_constraint = NULL,
  bias_constraint = NULL,
  dropout = 0,
  recurrent_dropout = 0,
  seed = NULL,
  ...
)
```

## Arguments

| | |
|---|---|
| units | Positive integer, dimensionality of the output space. |
| activation | Activation function to use. Default: hyperbolic tangent (tanh). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x). |
| recurrent_activation | Activation function to use for the recurrent step. Default: sigmoid (sigmoid). If you pass NULL, no activation is applied (ie. "linear" activation: a(x) = x). |
| use_bias | Boolean, (default TRUE), whether the layer should use a bias vector. |
| kernel_initializer | Initializer for the kernel weights matrix, used for the linear transformation of the inputs. Default: "glorot_uniform". |
| recurrent_initializer | Initializer for the recurrent_kernel weights matrix, used for the linear transformation of the recurrent state. Default: "orthogonal". |
| bias_initializer | Initializer for the bias vector. Default: "zeros". |
| unit_forget_bias | Boolean (default TRUE). If TRUE, add 1 to the bias of the forget gate at initialization. Setting it to TRUE will also force bias_initializer="zeros". This is recommended in Jozefowicz et al. |
| kernel_regularizer | Regularizer function applied to the kernel weights matrix. Default: NULL. |
| recurrent_regularizer | Regularizer function applied to the recurrent_kernel weights matrix. Default: NULL. |
| bias_regularizer | Regularizer function applied to the bias vector. Default: NULL. |
| kernel_constraint | Constraint function applied to the kernel weights matrix. Default: NULL. |
| recurrent_constraint | Constraint function applied to the recurrent_kernel weights matrix. Default: NULL. |
| bias_constraint | Constraint function applied to the bias vector. Default: NULL. |
| dropout | Float between 0 and 1. Fraction of the units to drop for the linear transformation of the inputs. Default: 0. |
| recurrent_dropout | Float between 0 and 1. Fraction of the units to drop for the linear transformation of the recurrent state. Default: 0. |
| seed | Random seed for dropout. |
| ... | For forward/backward compatability. |

## Value

A Layer instance, which is intended to be used with layer_rnn().

## Call Arguments

- `inputs`: A 2D tensor, with shape `(batch, features)`.
- `states`: A 2D tensor with shape `(batch, units)`, which is the state from the previous time step.
- `training`: Boolean indicating whether the layer should behave in training mode or in inference mode. Only relevant when `dropout` or `recurrent_dropout` is used.

## Examples

```
inputs <- random_uniform(c(32, 10, 8))
output <- inputs |>
  layer_rnn(cell = rnn_cell_lstm(4))
shape(output)

## shape(32, 4)

rnn <- layer_rnn(cell = rnn_cell_lstm(4),
                 return_sequences = T,
                 return_state = T)
c(whole_sequence_output, ..final_state) %<-% rnn(inputs)
str(whole_sequence_output)

## <tf.Tensor: shape=(32, 10, 4), dtype=float32, numpy=. . . >

str(final_state)

## List of 2
##  $ :<tf.Tensor: shape=(32, 4), dtype=float32, numpy=. . . >
##  $ :<tf.Tensor: shape=(32, 4), dtype=float32, numpy=. . . >
```

rnn_cell_simple *Cell class for SimpleRNN.*

## Description

This class processes one step within the whole time sequence input, whereas `layer_simple_rnn()` processes the whole sequence.

## Usage

```
rnn_cell_simple(
  units,
  activation = "tanh",
  use_bias = TRUE,
  kernel_initializer = "glorot_uniform",
  recurrent_initializer = "orthogonal",
  bias_initializer = "zeros",
  kernel_regularizer = NULL,
  recurrent_regularizer = NULL,
  bias_regularizer = NULL,
  kernel_constraint = NULL,
  recurrent_constraint = NULL,
  bias_constraint = NULL,
  dropout = 0,
  recurrent_dropout = 0,
  seed = NULL,
  ...
)
```

## Arguments

| | |
|---|---|
| `units` | Positive integer, dimensionality of the output space. |
| `activation` | Activation function to use. Default: hyperbolic tangent (`tanh`). If you pass `NULL`, no activation is applied (ie. "linear" activation: `a(x) = x`). |
| `use_bias` | Boolean, (default `TRUE`), whether the layer should use a bias vector. |
| `kernel_initializer` | Initializer for the `kernel` weights matrix, used for the linear transformation of the inputs. Default: `"glorot_uniform"`. |
| `recurrent_initializer` | Initializer for the `recurrent_kernel` weights matrix, used for the linear transformation of the recurrent state. Default: `"orthogonal"`. |
| `bias_initializer` | Initializer for the bias vector. Default: `"zeros"`. |
| `kernel_regularizer` | Regularizer function applied to the `kernel` weights matrix. Default: `NULL`. |

recurrent_regularizer
: Regularizer function applied to the recurrent_kernel weights matrix. Default: NULL.

bias_regularizer
: Regularizer function applied to the bias vector. Default: NULL.

kernel_constraint
: Constraint function applied to the kernel weights matrix. Default: NULL.

recurrent_constraint
: Constraint function applied to the recurrent_kernel weights matrix. Default: NULL.

bias_constraint
: Constraint function applied to the bias vector. Default: NULL.

dropout
: Float between 0 and 1. Fraction of the units to drop for the linear transformation of the inputs. Default: 0.

recurrent_dropout
: Float between 0 and 1. Fraction of the units to drop for the linear transformation of the recurrent state. Default: 0.

seed
: Random seed for dropout.

...
: For forward/backward compatability.

## Value

A Layer instance, which is intended to be used with layer_rnn().

## Call Arguments

- sequence: A 2D tensor, with shape (batch, features).
- states: A 2D tensor with shape (batch, units), which is the state from the previous time step.
- training: Python boolean indicating whether the layer should behave in training mode or in inference mode. Only relevant when dropout or recurrent_dropout is used.

## Examples

```
inputs <- random_uniform(c(32, 10, 8))
rnn <- layer_rnn(cell = rnn_cell_simple(units = 4))
output <- rnn(inputs)  # The output has shape `(32, 4)`.
rnn <- layer_rnn(
    cell = rnn_cell_simple(units = 4),
    return_sequences=TRUE,
    return_state=TRUE
)
# whole_sequence_output has shape `(32, 10, 4)`.
# final_state has shape `(32, 4)`.
c(whole_sequence_output, final_state) %<-% rnn(inputs)
```

---

`save_model` *Saves a model as a* `.keras` *file.*

---

## Description

Saves a model as a `.keras` file.

## Usage

```
save_model(model, filepath = NULL, overwrite = FALSE, zipped = NULL, ...)
```

## Arguments

| | |
|---|---|
| `model` | A keras model. |
| `filepath` | string, Path where to save the model. Must end in `.keras`. |
| `overwrite` | Whether we should overwrite any existing model at the target location, or instead ask the user via an interactive prompt. |
| `zipped` | Whether to save the model as a zipped `.keras` archive (default when saving locally), or as an unzipped directory (default when saving on the Hugging Face Hub). |
| `...` | For forward/backward compatability. |

## Value

If `filepath` is provided, then this function is called primarily for side effects, and `model` is returned invisibly. If `filepath` is not provided or `NULL`, then the serialized model is returned as an R raw vector.

## Examples

```
model <- keras_model_sequential(input_shape = c(3)) |>
  layer_dense(5) |>
  layer_activation_softmax()

model |> save_model("model.keras")
loaded_model <- load_model("model.keras")

x <- random_uniform(c(10, 3))
stopifnot(all.equal(
  model |> predict(x),
  loaded_model |> predict(x)
))
```

The saved `.keras` file is a `zip` archive that contains:

- The model's configuration (architecture)
- The model's weights
- The model's optimizer's state (if any)

Thus models can be reinstantiated in the exact same state.

```
zip::zip_list("model.keras")[, "filename"]
```

```
## [1] "metadata.json"    "config.json"      "model.weights.h5"
```

## See Also

`load_model()`

`load_model_weights()`
`register_keras_serializable()`
`save_model_config()`
`save_model_weights()`
`with_custom_object_scope()`

save_model_config *Save and load model configuration as JSON*

## Description

Save and re-load models configurations as JSON. Note that the representation does not include the weights, only the architecture.

## Usage

```
save_model_config(model, filepath = NULL, overwrite = FALSE)

load_model_config(filepath, custom_objects = NULL)
```

## Arguments

| | |
|---|---|
| model | Model object to save |
| filepath | path to json file with the model config. |
| overwrite | Whether we should overwrite any existing model configuration json at filepath, or instead ask the user via an interactive prompt. |
| custom_objects | Optional named list mapping names to custom classes or functions to be considered during deserialization. |

## Details

Note: save_model_config() serializes the model to JSON using serialize_keras_object(), not get_config(). serialize_keras_object() returns a superset of get_config(), with additional information needed to create the class object needed to restore the model. See example for how to extract the get_config() value from a saved model.

## Value

This is called primarily for side effects. model is returned, invisibly, to enable usage with the pipe.

## Example

```
model <- keras_model_sequential(input_shape = 10) |> layer_dense(10)
file <- tempfile("model-config-", fileext = ".json")
save_model_config(model, file)

# load a new model instance with the same architecture but different weights
model2 <- load_model_config(file)

stopifnot(exprs = {
  all.equal(get_config(model), get_config(model2))

  # To extract the `get_config()` value from a saved model config:
```

```
  all.equal(
      get_config(model),
      structure(jsonlite::read_json(file)$config,
                "__class__" = keras_model_sequential()$`__class__`)
  )
})
```

save_model()
save_model_weights()
with_custom_object_scope()

---

`save_model_weights` *Saves all weights to a single file or sharded files.*

---

## Description

By default, the weights are saved in a single `.weights.h5` file. Enable sharding via `max_shard_size` to split weights across multiple files (in GB) and produce a `.weights.json` manifest that tracks shard metadata.

The saved sharded files contain:

- `*.weights.json`: configuration file containing `metadata` and `weight_map` entries.
- `*_xxxxxx.weights.h5`: weight shards limited by `max_shard_size`.

```
model <-
  keras_model_sequential(input_shape = 2) |>
  layer_dense(4)

path_h5 <- tempfile(fileext = ".weights.h5")
path_json <- tempfile(fileext = ".weights.json")

model |> save_model_weights(path_h5)
model |> save_model_weights(path_json, max_shard_size = 0.01)

model |> load_model_weights(path_h5)
model |> load_model_weights(path_json)
```

### Usage

```
save_model_weights(model, filepath, overwrite = FALSE, max_shard_size = NULL)
```

### Arguments

| | |
|---|---|
| model | A keras Model object. |
| filepath | Path where the weights will be saved. Accepts .weights.h5, or when sharding is enabled, a .weights.json manifest path. If .weights.h5 is provided while sharding, the filename will be overridden to end in .weights.json. |
| overwrite | Whether to overwrite any existing weights at the target location, or instead ask the user via an interactive prompt. |
| max_shard_size | Numeric size in GB for each sharded file. Use NULL to disable sharding. |

### Value

This is called primarily for side effects. model is returned, invisibly, to enable usage with the pipe.

---

## serialize_keras_object

*Retrieve the full config by serializing the Keras object.*

---

### Description

serialize_keras_object() serializes a Keras object to a named list that represents the object, and is a reciprocal function of deserialize_keras_object(). See deserialize_keras_object() for more information about the full config format.

### Usage

```
serialize_keras_object(obj)
```

### Arguments

| | |
|---|---|
| obj | the Keras object to serialize. |

### Value

A named list that represents the object config. The config is expected to contain simple types only, and can be saved as json. The object can be deserialized from the config via `deserialize_keras_object()`.

### See Also

- https://keras.io/api/models/model_saving_apis/serialization_utils#serializekerasobject-functior

`register_keras_serializable()`
`with_custom_object_scope()`

---

## set_random_seed *Sets all random seeds (Python, NumPy, and backend framework, e.g. TF).*

---

### Description

You can use this utility to make almost any Keras program fully deterministic. Some limitations apply in cases where network communications are involved (e.g. parameter server distribution), which creates additional sources of randomness, or when certain non-deterministic cuDNN ops are involved.

This sets:

- the R session seed: `set.seed()`
- the Python session seed: `import random; random.seed(seed)`
- the Python NumPy seed: `import numpy; numpy.random.seed(seed)`
- the TensorFlow seed: `tf$random$set_seed(seed)` (only if TF is installed)
- The Torch seed: `import("torch")$manual_seed(seed)` (only if the backend is torch)
- and disables Python hash randomization.

Note that the TensorFlow seed is set even if you're not using TensorFlow as your backend framework, since many workflows leverage `tf$data` pipelines (which feature random shuffling). Likewise many workflows might leverage NumPy APIs.

### Usage

```
set_random_seed(seed)
```

### Arguments

| | |
|---|---|
| seed | Integer, the random seed to use. |

### Value

No return value, called for side effects.

### See Also

## set_state_tree *Assigns values to variables of the model.*

---

### Description

This method takes a dictionary (named list) of nested variable values, which represents the state tree of the model, and assigns them to the corresponding variables of the model. The keys (list names) represent the variable names (e.g., 'trainable_variables', 'optimizer_variables'), and the values are nested dictionaries containing the variable paths and their corresponding values.

## Usage

```
set_state_tree(object, state_tree)
```

## Arguments

| | |
|---|---|
| object | A keras model. |
| state_tree | A dictionary representing the state tree of the model. The keys are the variable names, and the values are nested dictionaries representing the variable paths and their values. |

## See Also

summary.keras.src.models.model.Model()

---

# shape *Tensor shape utility*

---

## Description

This function can be used to get or create a tensor shape.

## Usage

```
shape(...)

## S3 method for class 'keras_shape'
format(x, ..., prefix = TRUE)

## S3 method for class 'keras_shape'
print(x, ...)

## S3 method for class 'keras_shape'
x[...]

## S3 method for class 'keras_shape'
as.integer(x, ...)

## S3 method for class 'keras_shape'
```

```
Summary(..., na.rm = FALSE)

## S3 method for class 'keras_shape'
as.list(x, ...)

## S3 method for class 'keras_shape'
x == y

## S3 method for class 'keras_shape'
x != y
```

## Arguments

| | |
|---|---|
| ... | A shape specification. Numerics, NULL and tensors are valid. NULL, NA, and -1L can be used to specify an unspecified dim size. Tensors are dispatched to op_shape() to extract the tensor shape. Values wrapped in I() are used asis (see examples). All other objects are coerced via as.integer(). |
| x, y | A keras_shape object. |
| prefix | Whether to format the shape object with a prefix. Defaults to "shape". |
| na.rm | passed on to Summary group generics like prod(). Unknown axes are treated as NA. |

## Value

A list with a "keras_shape" class attribute. Each element of the list will be either a) NULL, b) an R integer or c) a scalar integer tensor (e.g., when supplied a TF tensor with an unspecified dimension in a function being traced).

## Examples

```
shape(1, 2, 3)

## shape(1, 2, 3)
```

3 ways to specify an unknown dimension

```
shape(NA,   2, 3)
shape(NULL, 2, 3)
shape(-1,   2, 3)

## shape(NA, 2, 3)
## shape(NA, 2, 3)
## shape(NA, 2, 3)
```

Most functions that take a 'shape' argument also coerce with shape()

```
layer_input(c(1, 2, 3))
layer_input(shape(1, 2, 3))

## <KerasTensor shape=(None, 1, 2, 3), dtype=float32, sparse=False, ragged=False, name=keras_tensor>
## <KerasTensor shape=(None, 1, 2, 3), dtype=float32, sparse=False, ragged=False, name=keras_tensor_1>
```

You can also use `shape()` to get the shape of a tensor (excepting scalar integer tensors).

```
symbolic_tensor <- layer_input(shape(1, 2, 3))
shape(symbolic_tensor)

## shape(NA, 1, 2, 3)

eager_tensor <- op_ones(c(1,2,3))
shape(eager_tensor)

## shape(1, 2, 3)

op_shape(eager_tensor)

## shape(1, 2, 3)
```

Combine or expand shapes

```
shape(symbolic_tensor, 4)

## shape(NA, 1, 2, 3, 4)

shape(5, symbolic_tensor, 4)

## shape(5, NA, 1, 2, 3, 4)
```

Scalar integer tensors are treated as axis values. These are most commonly encountered when tracing a function in graph mode, where an axis size might be unknown.

```
tfn <- tensorflow::tf_function(function(x) {
  print(op_shape(x))
  x
},
input_signature = list(tensorflow::tf$TensorSpec(shape(1, NA, 3))))
invisible(tfn(op_ones(shape(1, 2, 3))))
```

```
## shape(1, Tensor("strided_slice:0", shape=(), dtype=int32), 3)
```

A useful pattern is to unpack the shape() with %<-%, like this:

```
c(batch_size, seq_len, channels) %<-% shape(x)

# `%<-%` also has support for skipping values
# during unpacking with `.` and `...`. For example,
# To retrieve just the first and/or last dim:
c(batch_size, ...) %<-% shape(x)
c(batch_size, ., .) %<-% shape(x)
c(..., channels) %<-% shape(x)
c(batch_size, ..., channels) %<-% shape(x)
c(batch_size, ., channels) %<-% shape(x)

echo_print <- function(x) {
  message("> ", deparse(substitute(x)));
  if(!is.null(x)) print(x)
}
tfn <- tensorflow::tf_function(function(x) {
  c(axis1, axis2, axis3) %<-% shape(x)
  echo_print(str(list(axis1 = axis1, axis2 = axis2, axis3 = axis3)))

  echo_print(shape(axis1))               # use axis1 tensor as axis value
  echo_print(shape(axis1, axis2, axis3)) # use axis1 tensor as axis value

  # use shape() to compose a new shape, e.g., in multihead attention
  n_heads <- 4
  echo_print(shape(axis1, axis2, n_heads, axis3/n_heads))

  x
},
input_signature = list(tensorflow::tf$TensorSpec(shape(NA, 4, 16))))
invisible(tfn(op_ones(shape(2, 4, 16))))

## > str(list(axis1 = axis1, axis2 = axis2, axis3 = axis3))

## List of 3
##  $ axis1:<tf.Tensor 'strided_slice:0' shape=() dtype=int32>
##  $ axis2: int 4
##  $ axis3: int 16

## > shape(axis1)

## shape(Tensor("strided_slice:0", shape=(), dtype=int32))
```

```
## > shape(axis1, axis2, axis3)

## shape(Tensor("strided_slice:0", shape=(), dtype=int32), 4, 16)

## > shape(axis1, axis2, n_heads, axis3/n_heads)

## shape(Tensor("strided_slice:0", shape=(), dtype=int32), 4, 4, 4)
```

If you want to resolve the shape of a tensor that can potentially be a scalar integer, you can wrap the tensor in `I()`, or use `op_shape()`.

```
(x <- op_convert_to_tensor(2L))

## tf.Tensor(2, shape=(), dtype=int32)

# by default, shape() treats scalar integer tensors as axis values
shape(x)

## shape(tf.Tensor(2, shape=(), dtype=int32))

# to access the shape of a scalar integer,
# call `op_shape()`, or protect with `I()`
op_shape(x)

## shape()

shape(I(x))

## shape()
```

## See Also

`op_shape()`

split_dataset *Splits a dataset into a left half and a right half (e.g. train / test).*

## Description

Splits a dataset into a left half and a right half (e.g. train / test).

## Usage

```
split_dataset(
  dataset,
  left_size = NULL,
  right_size = NULL,
  shuffle = FALSE,
  seed = NULL
)
```

## Arguments

| | |
|---|---|
| dataset | A `tf$data$Dataset`, a `torch$utils$data$Dataset` object, or a list of arrays with the same length. |
| left_size | If float (in the range `[0, 1]`), it signifies the fraction of the data to pack in the left dataset. If integer, it signifies the number of samples to pack in the left dataset. If `NULL`, defaults to the complement to `right_size`. Defaults to `NULL`. |
| right_size | If float (in the range `[0, 1]`), it signifies the fraction of the data to pack in the right dataset. If integer, it signifies the number of samples to pack in the right dataset. If `NULL`, defaults to the complement to `left_size`. Defaults to `NULL`. |
| shuffle | Boolean, whether to shuffle the data before splitting it. |
| seed | A random seed for shuffling. |

## Value

A list of two `tf$data$Dataset` objects: the left and right splits.

## Examples

```
data <- random_uniform(c(1000, 4))
c(left_ds, right_ds) %<-% split_dataset(list(data$numpy()), left_size = 0.8)
left_ds$cardinality()

## tf.Tensor(800, shape=(), dtype=int64)

right_ds$cardinality()

## tf.Tensor(200, shape=(), dtype=int64)
```

`summary.keras.src.models.model.Model`

*Print a summary of a Keras Model*

---

## Description

Print a summary of a Keras Model

## Usage

```
## S3 method for class 'keras.src.models.model.Model'
summary(object, ...)

## S3 method for class 'keras.src.models.model.Model'
format(
  x,
  line_length = min(getOption("width"), 180),
  positions = NULL,
  expand_nested = FALSE,
  show_trainable = NA,
  ...,
  layer_range = NULL,
  compact = TRUE
)

## S3 method for class 'keras.src.models.model.Model'
print(x, ...)
```

## Arguments

| | |
|---|---|
| object, x | Keras model instance |
| ... | for summary() and print(), passed on to format(). For format(), passed on to model$summary(). |
| line_length | Total length of printed lines |
| positions | Relative or absolute positions of log elements in each line. If not provided, defaults to c(0.33, 0.55, 0.67, 1.0). |
| expand_nested | Whether to expand the nested models. If not provided, defaults to FALSE. |
| show_trainable | Whether to show if a layer is trainable. If not provided, defaults to FALSE. |
| layer_range | a list, tuple, or vector of 2 strings, which is the starting layer name and ending layer name (both inclusive) indicating the range of layers to be printed in summary. It also accepts regex patterns instead of exact name. In such case, start predicate will be the first element it matches to layer_range[[1]] and the end predicate will be the last element it matches to layer_range[[1]]. By default NULL which considers all layers of model. |
| compact | Whether to remove white-space only lines from the model summary. (Default TRUE) |

## Value

format() returns a length 1 character vector. print() returns the model object invisibly. summary() returns the output of format() invisibly after printing it.

## Enabling color output in Knitr (RMarkdown, Quarto)

In order to enable color output in a quarto or rmarkdown document with an html output format (include revealjs presentations), then you will need to do the following in a setup chunk:

```
```{r setup, include = FALSE}
options(cli.num_colors = 256)
fansi::set_knit_hooks(knitr::knit_hooks)
options(width = 75) # adjust as needed for format
```
```

---

`test_on_batch` *Test the model on a single batch of samples.*

---

## Description

Test the model on a single batch of samples.

## Usage

```
test_on_batch(object, x, y = NULL, sample_weight = NULL, ...)
```

## Arguments

| | |
|---|---|
| `object` | Keras model object |
| `x` | Input data. Must be array-like. |
| `y` | Target data. Must be array-like. |
| `sample_weight` | Optional array of the same length as x, containing weights to apply to the model's loss for each sample. In the case of temporal data, you can pass a 2D array with shape `(samples, sequence_length)`, to apply a different weight to every timestep of every sample. |
| `...` | for forward/backward compatability |

## Value

A scalar loss value (when no metrics), or a named list of loss and metric values (if there are metrics).

---

`text_dataset_from_directory` *Generates a* `tf.data.Dataset` *from text files in a directory.*

---

## Description

If your directory structure is:

```
main_directory/
...class_a/
......a_text_1.txt
......a_text_2.txt
...class_b/
......b_text_1.txt
......b_text_2.txt
```

Then calling `text_dataset_from_directory(main_directory, labels='inferred')` will return a `tf.data.Dataset` that yields batches of texts from the subdirectories `class_a` and `class_b`, together with labels 0 and 1 (0 corresponding to `class_a` and 1 corresponding to `class_b`).

Only `.txt` files are supported at this time.

## Usage

```
text_dataset_from_directory(
  directory,
  labels = "inferred",
  label_mode = "int",
  class_names = NULL,
  batch_size = 32L,
  max_length = NULL,
  shuffle = TRUE,
  seed = NULL,
  validation_split = NULL,
  subset = NULL,
  follow_links = FALSE,
  verbose = TRUE
)
```

## Arguments

| | |
|---|---|
| directory | Directory where the data is located. If labels is "inferred", it should contain subdirectories, each containing text files for a class. Otherwise, the directory structure is ignored. |
| labels | Either "inferred" (labels are generated from the directory structure), NULL (no labels), or a list/tuple of integer labels of the same size as the number of text files found in the directory. Labels should be sorted according to the alphanumeric order of the text file paths (obtained via os.walk(directory) in Python). |
| label_mode | String describing the encoding of labels. Options are:<br>• "int": means that the labels are encoded as integers (e.g. for sparse_categorical_crossentropy loss).<br>• "categorical" means that the labels are encoded as a categorical vector (e.g. for categorical_crossentropy loss).<br>• "binary" means that the labels (there can be only 2) are encoded as float32 scalars with values 0 or 1 (e.g. for binary_crossentropy).<br>• NULL (no labels). |
| class_names | Only valid if "labels" is "inferred". This is the explicit list of class names (must match names of subdirectories). Used to control the order of the classes (otherwise alphanumerical order is used). |
| batch_size | Size of the batches of data. If NULL, the data will not be batched (the dataset will yield individual samples). Defaults to 32. |
| max_length | Maximum size of a text string. Texts longer than this will be truncated to max_length. |
| shuffle | Whether to shuffle the data. If set to FALSE, sorts the data in alphanumeric order. Defaults to TRUE. |
| seed | Optional random seed for shuffling and transformations. |
| validation_split | Optional float between 0 and 1, fraction of data to reserve for validation. |
| subset | Subset of the data to return. One of "training", "validation" or "both". Only used if validation_split is set. When subset="both", the utility returns a tuple of two datasets (the training and validation datasets respectively). |
| follow_links | Whether to visits subdirectories pointed to by symlinks. Defaults to FALSE. |
| verbose | Whether to display number information on classes and number of files found. Defaults to TRUE. |

## Value

A tf.data.Dataset object.

- If label_mode is NULL, it yields string tensors of shape (batch_size,), containing the contents of a batch of text files.
- Otherwise, it yields a tuple (texts, labels), where texts has shape (batch_size,) and labels follows the format described below.

Rules regarding labels format:

- if `label_mode` is `int`, the labels are an `int32` tensor of shape `(batch_size,)`.
- if `label_mode` is `binary`, the labels are a `float32` tensor of 1s and 0s of shape `(batch_size, 1)`.
- if `label_mode` is `categorical`, the labels are a `float32` tensor of shape `(batch_size, num_classes)`, representing a one-hot encoding of the class index.

`timeseries_dataset_from_array` *Creates a dataset of sliding windows over a timeseries provided as array.*

## Description

This function takes in a sequence of data-points gathered at equal intervals, along with time series parameters such as length of the sequences/windows, spacing between two sequence/windows, etc., to produce batches of timeseries inputs and targets.

## Usage

```
timeseries_dataset_from_array(
  data,
  targets,
  sequence_length,
  sequence_stride = 1L,
  sampling_rate = 1L,
  batch_size = 128L,
  shuffle = FALSE,
  seed = NULL,
  start_index = NULL,
  end_index = NULL
)
```

## Arguments

| | |
|---|---|
| `data` | array or eager tensor containing consecutive data points (timesteps). The first dimension is expected to be the time dimension. |
| `targets` | Targets corresponding to timesteps in `data`. `targets[i]` should be the target corresponding to the window that starts at index `i` (see example 2 below). Pass `NULL` if you don't have target data (in this case the dataset will only yield the input data). |
| `sequence_length` | Length of the output sequences (in number of timesteps). |
| `sequence_stride` | Period between successive output sequences. For stride `s`, output samples would start at index `data[i]`, `data[i + s]`, `data[i + 2 * s]`, etc. |
| `sampling_rate` | Period between successive individual timesteps within sequences. For rate `r`, timesteps `data[i], data[i + r], ... data[i + sequence_length]` are used for creating a sample sequence. |
| `batch_size` | Number of timeseries samples in each batch (except maybe the last one). If `NULL`, the data will not be batched (the dataset will yield individual samples). |
| `shuffle` | Whether to shuffle output samples, or instead draw them in chronological order. |

| | |
|---|---|
| seed | Optional int; random seed for shuffling. |
| start_index | Optional int; data points earlier (exclusive) than start_index will not be used in the output sequences. This is useful to reserve part of the data for test or validation. |
| end_index | Optional int; data points later (exclusive) than end_index will not be used in the output sequences. This is useful to reserve part of the data for test or validation. |

## Value

A tf$data$Dataset instance. If targets was passed, the dataset yields list (batch_of_sequences, batch_of_targets). If not, the dataset yields only batch_of_sequences.

Example 1:

Consider indices [0, 1, ... 98]. With sequence_length=10, sampling_rate=2, sequence_stride=3, shuffle=FALSE, the dataset will yield batches of sequences composed of the following indices:

```
First sequence:  [0  2  4  6  8 10 12 14 16 18]
Second sequence: [3  5  7  9 11 13 15 17 19 21]
Third sequence:  [6  8 10 12 14 16 18 20 22 24]
...
Last sequence:   [78 80 82 84 86 88 90 92 94 96]
```

In this case the last 2 data points are discarded since no full sequence can be generated to include them (the next sequence would have started at index 81, and thus its last step would have gone over 98).

Example 2: Temporal regression.

Consider an array data of scalar values, of shape (steps,). To generate a dataset that uses the past 10 timesteps to predict the next timestep, you would use:

```
data <- op_array(1:20)
input_data <- data[1:10]
targets <- data[11:20]
dataset <- timeseries_dataset_from_array(
  input_data, targets, sequence_length=10)
iter <- reticulate::as_iterator(dataset)
reticulate::iter_next(iter)

## [[1]]
## tf.Tensor([[ 1  2  3  4  5  6  7  8  9 10]], shape=(1, 10), dtype=int32)
##
## [[2]]
## tf.Tensor([11], shape=(1), dtype=int32)
```

Example 3: Temporal regression for many-to-many architectures.

Consider two arrays of scalar values X and Y, both of shape (100,). The resulting dataset should consist samples with 20 timestamps each. The samples should not overlap. To generate a dataset that uses the current timestamp to predict the corresponding target timestep, you would use:

```
X <- op_array(1:100)
Y <- X*2

sample_length <- 20
input_dataset <- timeseries_dataset_from_array(
    X, NULL, sequence_length=sample_length, sequence_stride=sample_length)
target_dataset <- timeseries_dataset_from_array(
    Y, NULL, sequence_length=sample_length, sequence_stride=sample_length)

inputs <- reticulate::as_iterator(input_dataset) %>% reticulate::iter_next()
targets <- reticulate::as_iterator(target_dataset) %>% reticulate::iter_next()
```

---

to_categorical *Converts a class vector (integers) to binary class matrix.*

---

## Description

E.g. for use with loss_categorical_crossentropy().

## Usage

```
to_categorical(x, num_classes = NULL)
```

## Arguments

| | |
|---|---|
| x | Array-like with class values to be converted into a matrix (integers from 0 to num_classes - 1). R factors are coerced to integer and offset to be 0-based, i.e., as.integer(x) - 1L. |
| num_classes | Total number of classes. If NULL, this would be inferred as max(x) + 1. Defaults to NULL. |

## Value

A binary matrix representation of the input as an R array. The class axis is placed last.

## Examples

```
a <- to_categorical(c(0, 1, 2, 3), num_classes=4)
print(a)

##      [,1] [,2] [,3] [,4]
## [1,]    1    0    0    0
## [2,]    0    1    0    0
## [3,]    0    0    1    0
## [4,]    0    0    0    1

b <- array(c(.9, .04, .03, .03,
             .3, .45, .15, .13,
             .04, .01, .94, .05,
             .12, .21, .5, .17),
             dim = c(4, 4))
loss <- op_categorical_crossentropy(a, b)
loss
```

```
## tf.Tensor([0.41284522 0.45601739 0.54430155 0.80437282], shape=(4), dtype=float64)
```

```
loss <- op_categorical_crossentropy(a, a)
loss
```

```
## tf.Tensor([1.00000005e-07 1.00000005e-07 1.00000005e-07 1.00000005e-07], shape=(4), dtype=float64)
```

`train_on_batch` *Runs a single gradient update on a single batch of data.*

## Description

Runs a single gradient update on a single batch of data.

## Usage

```
train_on_batch(object, x, y = NULL, sample_weight = NULL, class_weight = NULL)
```

## Arguments

| | |
|---|---|
| `object` | Keras model object |
| `x` | Input data. Must be array-like. |
| `y` | Target data. Must be array-like. |
| `sample_weight` | Optional array of the same length as x, containing weights to apply to the model's loss for each sample. In the case of temporal data, you can pass a 2D array with shape `(samples, sequence_length)`, to apply a different weight to every timestep of every sample. |
| `class_weight` | Optional named list mapping class indices (integers, 0-based) to a weight (float) to apply to the model's loss for the samples from this class during training. This can be useful to tell the model to "pay more attention" to samples from an under-represented class. When `class_weight` is specified and targets have a rank of 2 or greater, either `y` must be one-hot encoded, or an explicit final dimension of 1 must be included for sparse class labels. |

## Value

A scalar loss value (when no metrics), or a named list of loss and metric values (if there are metrics). The property `model$metrics_names` will give you the display labels for the scalar outputs.

use_backend *Configure a Keras backend*

## Description

Configure a Keras backend

## Usage

```
use_backend(backend, gpu = NA)
```

## Arguments

| | |
|---|---|
| backend | string, can be "tensorflow", "jax", "numpy", or "torch". |
| gpu | bool, whether to use the GPU. If NA (default), it will attempt to detect GPU availability on Linux. On macOS and Windows it defaults to FALSE. |

## Details

These functions allow configuring which backend keras will use. Note that only one backend can be configured at a time.

The function should be called after `library(keras3)` and before calling other functions within the package (see below for an example).

Note that macOS packages like `tensorflow-metal` and `jax-metal` that purportedly enabled GPU usage on M-series macs all are currently broken and seemingly abandoned.

There is experimental support for changing the backend after keras has initialized with `config_set_backend()`. Usage of `config_set_backend` is generally not recommended for regular workflow—restarting the R session is the only reliable way to change the backend.

```
library(keras3)
use_backend("tensorflow")
```

## Value

Called primarily for side effects. Returns the provided `backend`, invisibly.

`with_custom_object_scope` *Provide a scope with mappings of names to custom objects*

## Description

Provide a scope with mappings of names to custom objects

## Usage

```
with_custom_object_scope(objects, expr)
```

## Arguments

| | |
|---|---|
| `objects` | Named list of objects |
| `expr` | Expression to evaluate |

## Details

There are many elements of Keras models that can be customized with user objects (e.g. losses, metrics, regularizers, etc.). When loading saved models that use these functions you typically need to explicitly map names to user objects via the `custom_objects` parameter.

The `with_custom_object_scope()` function provides an alternative that lets you create a named alias for a user object that applies to an entire block of code, and is automatically recognized when loading saved models.

## Value

The result from evaluating `expr` within the custom object scope.

## Examples

```
# define custom metric
metric_top_3_categorical_accuracy <-
  custom_metric("top_3_categorical_accuracy", function(y_true, y_pred) {
    metric_top_k_categorical_accuracy(y_true, y_pred, k = 3)
  })

with_custom_object_scope(c(top_k_acc = sparse_top_k_cat_acc), {

  # ...define model...

  # compile model (refer to "top_k_acc" by name)
  model |> compile(
    loss = "binary_crossentropy",
    optimizer = optimizer_nadam(),
    metrics = c("top_k_acc")
```

```
  )

  # save the model
  model |> save_model("my_model.keras")

  # loading the model within the custom object scope doesn't
  # require explicitly providing the custom_object
  reloaded_model <- load_model("my_model.keras")
})
```

---

# zip_lists *Zip lists*

---

## Description

This is conceptually similar to `zip()` in Python, or R functions `purrr::transpose()` and `data.table::transpose()` (albeit, accepting elements in `...` instead of a single list), with one crucial difference: if the provided objects are named, then matching is done by names, not positions.

## Usage

```
zip_lists(...)
```

## Arguments

| | |
|---|---|
| `...` | R lists or atomic vectors, optionally named. |

## Details

All arguments supplied must be of the same length. If positional matching is required, then all arguments provided must be unnamed. If matching by names, then all arguments must have the same set of names, but they can be in different orders.

## Value

A inverted list
